FOREWORD

Minerals Yearbook, 1942, presents the achievements of the mineral industries of the United States during their first full year of World War II. It is a record of outstanding accomplishment to which the Nation can point with pride and satisfaction. It also provides convincing testimony on the vital importance of our great mineral wealth to the national security, for without our abundant mineral resources our unparalleled industrial strength would be impossible, and without our magnificent industrial machine the unprecedented production of munitions during 1942 could not have been attained. Thus in large measure our success in war on land or sea or in the air reflects our ability to provide those materials indispensable to modern warfare—metals and fuels and the other nonmetallic minerals.

Statistically the production of minerals in 1942 soared to new peaks in both quantity and value. For the first time in history, the aggregate value of mineral output exceeded $7,000,000,000. Certain branches of mining reported declines from the rates established in 1941, but production of many commodities reached new records, some of which probably will stand for many years or may never be equaled. Nevertheless, demand exceeded supplies, and the pressure for even greater output intensified as the year progressed. At the close of 1942, it was evident that production of many minerals would be limited by manpower shortages, while exhaustion of the reserves of a few commodities caused anxiety as to our ability to maintain current rates of production.

The Bureau of Mines played an increasingly vital role in the war program during 1942. Extensive exploration of mineral deposits was continued; new and improved methods of mineral beneficiation and recovery were developed; surveys of the production, distribution, consumption, and stocks of essential minerals were extended in scope and frequency; health and safety measures were furthered to reduce valuable time lost in the mines and mills from illness and injuries; provisions were made to protect the production, supply, storage, and transportation of indispensable minerals and mineral products from the mines, quarries, mills, and smelters; and closer contact was effected with Federal war agencies and private war industries in prosecuting the war. Most of these activities are only briefly mentioned in this volume, which is concerned principally with the accomplishments of the Bureau in economics and statistics. More complete data regarding the Bureau's work in technology, health, and safety can be found in the annual reports of the Secretary of the Interior and in other publications of the Bureau of Mines, although censorship precludes publication at this time of many of the results of investigations of strategic and critical minerals.

Distribution of the 1942 edition of Minerals Yearbook, as with the 1941 volume, will be restricted to Government offices engaged in war work. Many of the chapters of the 1941 volume dealing with nonstrategic commodities, minus complete data on foreign trade, were released for public distribution, but because of the refusal of the

Digitized by Google

censorship authorities to permit publication of foreign trade statistics most of these chapters for 1942 will be withheld. Only a few chapters, from which foreign trade statistics have been eliminated, because they have little significance, will be available for general distribution. To partly offset this disadvantage, the Bureau of Mines has expanded its usual published Mineral Industry Survey reports to include many of the statistical details on production, consumption, and stocks of the nonstrategic minerals that are customarily distributed to industry and the public in the preprint chapters of Minerals Yearbook. Minerals Yearbook will, of course, be available to the public after the war or whenever censorship restrictions are relaxed.

The mineral industries are to be commended for their cooperation in responding to Bureau of Mines surveys in spite of the numerous handicaps and urgent production schedules under which they operated in 1942. Thanks are gratefully extended to the thousands of mine, mill, and smelter operators, distributors, consumers, public officials and agencies, and trade journals who made generous contributions of data and advice, without which this volume could not be compiled. In this connection, especial mention should be made of the cooperation of State officials who have assisted in collecting mineral statistics within their respective jurisdictions, thus eliminating duplication and improving coverage and accuracy of data. State agents cooperating in the 1942 canvass were: Stewart J. Lloyd, acting State geologist, University, Ala.; Herman Gunter, State geologist, Tallahassee, Fla.; Garland Peyton, director, division of mines, mining, and geology, department of natural resources, Atlanta, Ga.; M. M. Leighton, chief, and Walter H. Voskuil, mineral economist, State geological survey division, Urbana, Ill.; A. C. Trowbridge, director, Iowa Geological Survey, Iowa City, Iowa; Raymond C. Moore, State geologist, Lawrence, Kans.; Edward B. Mathews, director, department of geology, mines, and water resources, board of natural resources, Baltimore, Md.; R. A. Smith, State geologist, Lansing, Mich.; H. A. Buehler, State geologist, Rolla, Mo.; Meredith E. Johnson, State geologist, Trenton, N. J.; C. A. Hartnagel, State geologist, New York State Museum, Albany, N. Y.; Jasper L. Stuckey, State geologist, Raleigh, N. C.; Robert H. Dott, director, Oklahoma Geological Survey, Norman, Okla.; E. P. Rothrock, State geologist, Vermillion, S. Dak.; E. H. Sellards, director, bureau of economic geology, Austin, Tex.; Arthur Bevan, State geologist, and Linwood H. Warwick, chief clerk, Virginia Geological Survey, Charlottesville, Va.; Harold E. Culver, supervisor, division of geology, department of conservation and development, Pullman, Wash.; Paul H. Price, State geologist, Morgantown, W. Va.; and E. F. Bean, State geologist, Madison, Wis. In addition, B. D. Stewart, department of mines, Juneau, Alaska, and Walter W. Bradley, State mineralogist, San Francisco, Calif., assisted in the compilation of statistics for Alaska and California, respectively.

INTRODUCTION

Considering the many difficulties of operation under wartime conditions, the mineral industries in 1942 established a remarkable record in supplying the essential needs of the United States for its military operations and civilian economy. This issue of Minerals Yearbook which records and analyzes the progress of the mineral industries during the year is therefore in essence a tribute to their achievements. The present expanded volume differs from its predecessors in a number of respects: It gives special attention to the significance of each of the many mineral commodities in the war program. It discusses the effects of the many emergency regulations of the Government upon the normal relationships of supply and demand. It provides more comprehensive data on ore reserves. It devotes additional space, in separate chapters, to titanium and nitrogen compounds. It accents the international aspects of mineral exploration, development, reserves, output, procurement, and use.

Because Minerals Yearbook, 1942, contains information on strategic and critical minerals, including full foreign trade data which censorship authorities have directed be withheld from the enemy, the volume has been classified as confidential. A few chapters dealing with nonstrategic commodities in which foreign trade is comparatively insignificant are being distributed to the public in preprint form without 1942 data on imports and exports. In the 1941 volume only 14 chapters were withheld from publication—those covering the highly strategic and critical items. The extension of censorship in the 1942 volume results largely from the ban on foreign trade figures. Statistical data for 1942 other than imports and exports for the nonstrategic minerals have been released through the Bureau's Mineral Industry Survey service.

Acknowledgments.—Thanks are gratefully extended to the Bituminous Coal Division, United States Department of the Interior, for its valuable contribution to the Yearbook in preparing the chapter covering the bituminous-coal industry. This division has supplied the chapter each year since the division was established in 1937.

The data on imports and exports in Minerals Yearbook were obtained through the cooperation of the United States Department of Commerce.

The Bureau of Mines was enabled to obtain the vast amount of statistical data included in Minerals Yearbook through the good will and cooperation of those interested in the mineral industries. The Bureau appreciates more than ever the contributions of data from the operators, distributors, consumers, public officials, trade associations, and others who have so kindly given of their time and effort to return questionnaires or supply information in other form.

Credit for the value and usefulness of the volume is also given to the many members of the Bureau's staff who assisted in the preparation, editing, and arrangement of the Yearbook material. Especial thanks are due the following members of the staff, who have been

most active and helpful in maintaining the high standards set for the Yearbook: Martha B. Clark, of the Economics and Statistics Service, for preparing the statistical summary of mineral production, and for ascertaining the accuracy, continuity, and uniformity of statistical data; Mabel E. Winslow, of the Office of Minerals Reports, for her excellent editorial work and advice; Louis F. Perry, of the Office of Minerals Reports, for his aid in preparing the charts; Max Abel, of the Economics and Statistics Service, for supervising the preparation of charts and assisting in the administrative details of the Yearbook program; and to the unnamed members of the Economics and Statistics Service who helped the authors in the preparation of their manuscripts.

INTRODUCTION

In the first year of World War II the mineral industry contributed metals, fuels, and other minerals—all indispensable for war—in quantities never before equaled. The physical volume of production was 3 percent more than in the previous record year 1941 and 21 percent higher than the predepression record of 1929; it exceeded the output in the war year 1918 by 54 percent. Owing to a moderate increase in mineral prices the value of production compared with 1941 was proportionately greater, having increased 10 percent to a new peak of $7,569,500,000, or 8 percent above the former record value of $6,981,340,000 established in 1920, when prices were abnormally high.

The outstanding performance for 1942 was achieved despite several factors that retarded production in some lines. Transportation bottlenecks forced severe curtailment of consumption of gasoline and fuel oil in the eastern region; as a result, the output of crude petroleum—in terms of value the largest item in the list of mineral products—declined slightly. Gold and silver production experienced the usual adverse effects of an ascending general price level and was also held back by scarcity of materials and manpower as well as the Government shut-down order effective late in the year. Price trends in 1942 did not favor the mineral industry, as mineral prices advanced only 7.5 percent over 1941, whereas the general price level rose 13 percent. Manpower shortages were felt in many branches besides precious metal mining. Preliminary figures indicate that the total number of men employed in producing minerals in 1942 was 3 percent lower than in 1941. Because of the scarcity of critical materials and manpower, several new projects that would have increased production could not be initiated.

Consumption of minerals also reached new heights in 1942 that surpassed the available supply from domestic sources. Despite the submarine menace, large quantities of foreign minerals were imported

Digitized by Google

but could not bridge the gap between domestic supply and potential demand. Consequently drastic conservation, substitution, and restrictive measures were adopted. Essential civilian requirements were cut deeply, and even allocations to war needs were subjected to rigid surveillance and limitation. The net result of the program was a gain in mineral inventories for the year. Thus at the end of 1942 the Nation's mineral-production facilities were operating at record rates, and a substantial reserve stock provided assurance that the essential war needs would not be severely impaired in 1943 for lack of raw materials.

PRODUCTION

Value of mineral output.—For the third consecutive year the quantity of minerals produced established a new all-time record, but the value of production exceeded the previous 1920 peak for the first time. Likewise, 1942 was the first year in which the value of domestic production, $7,569,500,000, reached the 7-billion mark. The former record year, 1920, $6,981,340,000, reflected the high prices of many minerals but chiefly the extraordinary prices for coal as exports soared because of the United Kingdom's inability (partly because of strikes) to meet heavy world demands. The value of the 1942 output was 10 percent greater than in 1941 and 29 percent over the predepression level of 1929.

Although dollar value is the only common denominator for measuring collectively the production of minerals of such diverse unit values as platinum and sand and gravel, it does not present a true picture of actual trends in the physical volume of production because of the influence of fluctuating prices. This fact is strikingly illustrated by comparing 1920 with 1942. The value of production in the latter year was only 8 percent above that of 1920, yet the physical volume of production, as measured by index numbers (in the computation of which the effects of price changes are largely eliminated), was 55 percent greater. Thus the growth of the mineral industry during this 22-year period and the industry's war contribution are not adequately revealed by a mere statement of value of output.

Of the total value of mineral production in 1942, fuels contributed $4,084,600,000 (54 percent), metals $2,361,800,000 (31 percent), and nonmetals other than fuels $1,123,100,000 (15 percent). Figure 1 shows the growth in value of various branches of mineral production from 1880 to 1942.

All major branches of mineral production—fuels, metals, and nonmetals—showed increased values in 1942. The value of the output of metals advanced 11 percent over 1941 and that of nonmetals other than fuels 8 percent; the value of fuels rose 10 percent. Oil and gas wells contributed a large proportion of the mineral output, with products valued at $2,452,700,000 in 1942—32 percent of the total and an increase of 5 percent over 1941. Hard- and soft-coal production was valued at $1,631,900,000, or 22 percent of the value of all mineral products and 19 percent more than the value of the 1941 coal output.

Trends in physical volume of production.—Figure 2 compares the physical volume of mineral production during the last 43 years with industrial and agricultural production and with population growth, each

Digitized by Google

expressed in terms of an index based on yearly averages for 1935–39.[1] The long-time trends of production during this 43-year period have been steadily upward, although year to year and cyclical fluctuations have been prominent. Production of minerals—the essential raw materials for industry—has been closely correlated with the trend of industrial production, experiencing the same ups and downs, whereas agricultural production has exhibited more moderate fluctuations and a growth line approximating the trend of population increase.

Because production of coal for domestic use and petroleum for automobile fuel, which has a pronounced effect on the trend of mineral output, does not respond proportionately to increases in the rate of

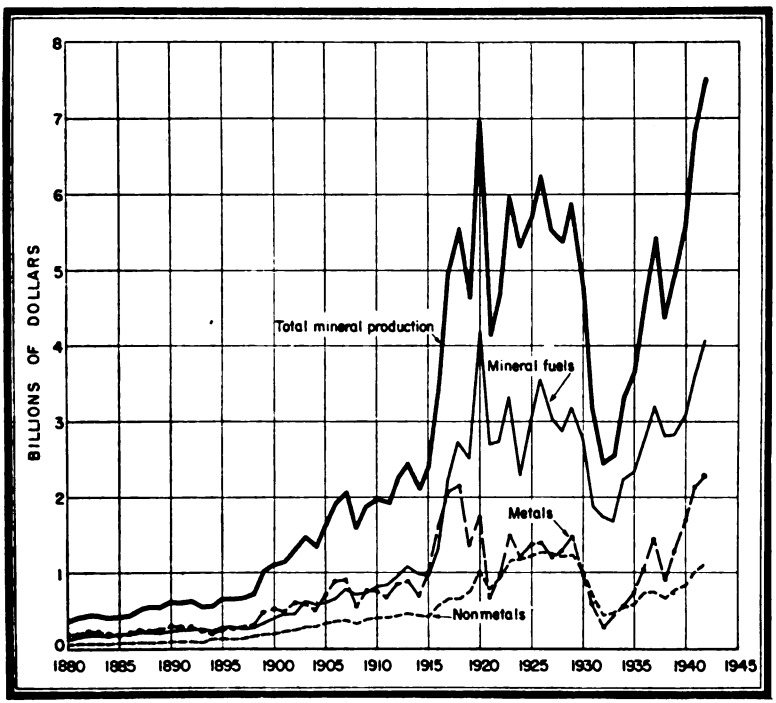

FIGURE 1.—Trends in value of mineral production in the United States, 1880–1942.

manufacturing activity and is more stable, the index of industrial production tends to exceed that of mineral production in periods of prosperity and to fall below during depressions. This characteristic explains in part the wide gaps between the two indexes in 1941 and 1942. Another factor is the extensive use of imported mineral raw materials in these years, which is reflected in the industrial index but not in the mineral index. It should also be noted that the Federal Reserve Board index of mineral production does not include certain mineral products, such as aluminum and magnesium, of which war use has increased greatly.

The production of many mineral commodities achieved new peaks in 1942. The light metals made outstanding advances; magne-

[1] The following indexes have been used—volume of farm production, U. S. Department of Agriculture; mineral production, 1900–1918, from Warren Persons' Forecasting Business Cycles; mineral production of 1919–42 and industrial production, Federal Reserve Board; total population of the United States, Bureau of the Census.

Digitized by Google

sium output increased threefold, bauxite more than doubled, and aluminum rose nearly 70 percent. Copper production broke the record established in 1916, and lead and zinc mine production also increased but failed to reach previous records. Iron ore, tungsten, molybdenum, and vanadium surpassed the high production rates of 1941, and chromite exceeded its 1918 peak. Manganese-ore production was considerably higher in 1942 than in 1941 but was below that during the last war. Except for petroleum (which declined from 1941) and anthracite, the output of fuels reached new highs in 1941, and bituminous coal broke a record that had stood since 1918.

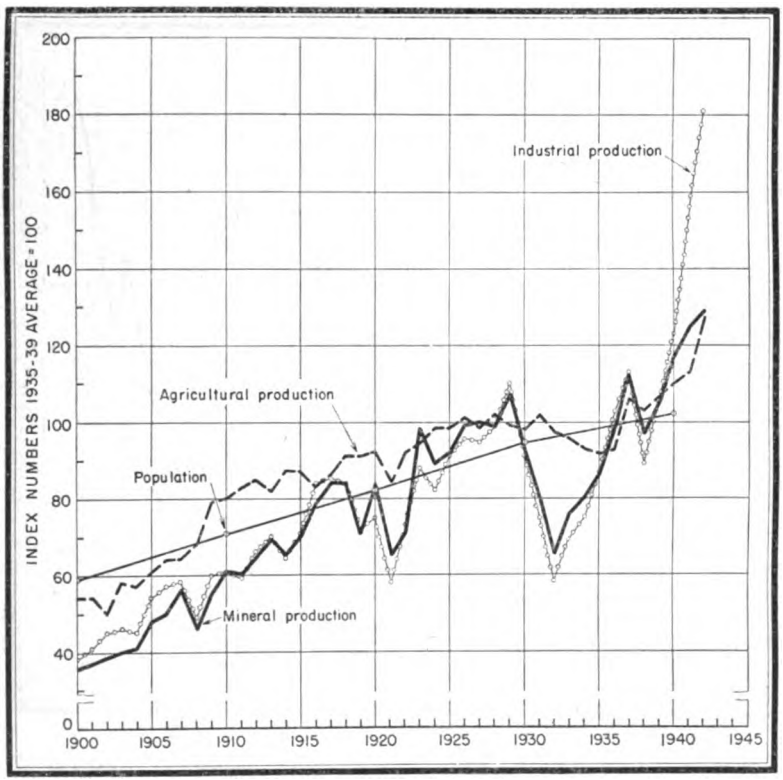

FIGURE 2.—Comparison of growth of physical volume of mineral production with that of agricultural and industrial production and population, 1900–1942.

Most of the building materials also set new high marks, reflecting the heavy war construction in 1942. Production of fluorspar, lime, potash, pyrites, sulfur, and salt advanced to new heights. Contrary to this pronounced upward trend were the decreases noted in the output of gold, silver, petroleum, asphalt, feldspar, gypsum, and phosphate rock.

STOCKS

Inventory-control schemes were in effect, directly or indirectly, for virtually all metals and important nonmetals during 1942. Idle, excessive, and enemy-owned inventories were also called upon to help effectuate the maximum output of war equipment and bolster

Digitized by Google

a shrinking volume of essential civilian supplies. Conservation, substitution and reclamation, fluctuating imports, and rapidly changing Lend-Lease needs affected relative requirements and resulted in shifts of position in critical mineral lists. As a result, there was a wide range in stock trends for individual minerals during the year, but on the whole there was a general, and in some items, a substantial, increase in stocks.

The primary acquisition of many minerals, and other commodities as well, by government agencies was greatly extended during the year. These purchases can no longer be considered as stock-pile accretions but only as inflow to a reservoir from which the discharge is channeled to the most desirable destination. In some commodities industry stocks were drawn upon for current needs while Government holdings were expanded; manganese ore, chromite, muscovite mica blocks and films, tin, molybdenum, and cadmium were typical examples. There was a net increase in the Nation's total inventory of the first three items; but stocks of tin, cadmium, and molybdenum declined, the last substantially. Industry and Government stocks of copper, lead, zinc, tungsten ore, vanadium, mica splittings, mercury, antimony, platinum, and bauxite were larger at the end of 1942 than at the beginning. There were also increases in industry stocks of nickel, acid-grade fluorspar, iron ore, and magnesium, whereas stocks of metallurgical-grade fluorspar and cement were lower. Consumers' stocks of pig iron declined moderately, but there were fairly heavy increases in consumers' and suppliers' stocks of scrap iron and steel. There was little change in stocks of anthracite, bituminous coal again showed an increase, and stocks of petroleum showed an over-all decrease.

CONSUMPTION

Mineral consumption again broke all records in 1942 and was still on a rising trend at the year end. For virtually all metals and some nonmetals, unrestricted demand would have exceeded supply but was held in check only by widespread curtailment of civilian uses. Even the amounts of materials for use in war essentials were subject to rigid scrutiny and limitation, and the substitution of less critical for more critical materials was actively pushed.

As the seriousness of the supply situation became apparent there was evolved a Production Requirements Plan (P. R. P.) in which the end use of the basic material was the governing factor in making allocations. It failed, however, to achieve the anticipated balance between supply and demand. Later in the year it was announced that the P. R. P. would be succeeded in 1943 by the Controlled Materials Plan (C. M. P.), which would be applied initially to aluminum, copper, and carbon and alloy steels. The new plan shifts control to the raw-materials source, thus requiring knowledge of material requirements throughout the manufacturing cycle down to the end product. By controlling allocations at the source, the balancing of allocations with available supply is facilitated. Responsibility for assembling estimates of raw-material requirements was placed with prime contractors, who are required to plan not only for their own needs but for those of their subcontractors and suppliers as well. Bills of materials so determined are then submitted to a

Digitized by Google

prime contractor's "claimant agency" of which seven were designated in the original order—Army, Navy, Maritime Commission, Board of Economic Warfare, etc. Each claimant agency assembles its bills of materials and submits them to the War Production Board, where they are balanced with available supply by a Requirements Committee and the respective controlled materials divisions of the War Production Board.

The year 1942 was characterized by a continuation of the war plant construction program, the near-conclusion of existing plant conversion and expansion, and a rapidly accelerated growth in war production. The thereby-expanded mineral needs are reflected by business indexes. The value of construction contracts awarded east of the Rocky Mountains (of which more than 80 percent were for public ownership) rose 37 percent from 1941 or to 8¼ billion dollars in 1942. Of the year's total, only 22 percent was for residential building, including a part applied to war housing. Of the remainder, 35 percent was for factory construction and 40 percent for public works and utilities. The Federal Reserve Board index for total construction (1923–25 equals 100) fluctuated monthly between 118 and 206 and averaged 166 for the year. For other than residential building the index increased from 149 in 1941 to 235, another new record. The adjusted index of total industrial production (1935–39 equals 100) continued the rise that began in the latter half of 1940, increased uninterruptedly from 171 in January 1942 to 197 in December, and averaged 181 for the year (unadjusted) compared with 156 in 1941 and 123 in 1940.

Consumption of minerals established many new highs in 1942. Among the metals, aluminum, chromite, copper, iron, magnesium, manganese ore, and other ferro-alloy elements reached new levels, but the use of tin, zinc, and lead declined under rigid control measures. Of the nonmetals, cement, lime, clay, fluorspar, sulfur, sand and gravel, phosphate rock, and potash exceeded previous records. In the fuel group, the demand for petroleum was held slightly under the 1941 peak by transportation difficulties; use of anthracite rose appreciably but still lagged behind the record, but bituminous-coal, natural-gas, and natural-gasoline consumption attained new peaks.

PRICES

A weighted average price for 24 major mineral commodities in 1942, which comprised over 98 percent of the total value of mineral production in that year, indicates an increase of 7.5 percent in producers' unit sales realizations compared with 1941. The average increase for the 9 metals in the group was 12.6 percent, that for the 5 fuels was 5.4 percent, and that for 10 other nonmetallic minerals was 5.3 percent. The relatively greater price rise for metals reflected premium prices paid by the Government for copper, lead, and zinc and the general pressure for increased metal production.

According to the Bureau of Labor Statistics, the wholesale price index (1926 equals 100) of metals and metal products rose from 99.4 in 1941 to 103.8 in 1942. The price index for nonferrous metals, which includes some fabricated products and excludes premium prices paid for copper, lead, and zinc, advanced from 84.4 to 85.7. Quoted prices for lead, zinc, antimony, cadmium, platinum, and mercury averaged higher in 1942 than in 1941; those of copper and

Digitized by Google

nickel were unchanged; and those of aluminum, magnesium, and tin declined, the last only slightly. The index for iron and steel products advanced less than 1 percent—from 96.4 to 97.2. Prices of ferrous raw materials, however, were virtually unchanged. Those for pig iron and most grades of scrap iron and steel were fixed throughout the year at ceiling prices; average pig iron and iron-ore prices for 1942 remained at 1941 levels, whereas the major scrap items were lower. Compared with 1941, fuel prices rose moderately. The price index for anthracite advanced from 82.7 to 85.5; bituminous coal from 104.3 to 109.7; and petroleum and its products from 57.0 to 59.8. Except for crushed stone and clay, which declined, building-material prices (brick and tile, cement, lime, and sand and gravel) increased, as did prices for phosphate rock and potash. The index price for all commodities rose 13 percent or from 87.3 in 1941 to 98.8 in 1942.

Mineral prices again lagged appreciably behind those for all commodities in 1942; the former increased only 7.5 percent over 1941, whereas the general price level rose 13 percent. Compared with 1929, the general price index in 1942 had increased 3.7 percent, whereas the index for fuels and lighting materials declined 5.4 percent (the index for petroleum and products dropped 16.1 percent), nonferrous metals 19.2 percent, and fertilizer materials 17.7 percent; the iron and steel price index rose 2.4 percent. Prices for nonmetallic minerals other than those included above averaged lower in 1942 than in 1929. In comparison with prices that prevailed in the First World War, when needs were far below those of the present, the price index for all commodities in 1942 was about a quarter below, whereas the indexes for important mineral groups, iron and steel, nonferrous metals, and petroleum and its products, were one-third to one-half under those of 1918.

EMPLOYMENT

In contrast to the serious unemployment in the mineral industries a decade ago, major segments experienced a severe shortage of labor in 1942, particularly as regards workers in nonferrous and ferro-alloy fields. The exceptional demand for most of those metals required an increase of the labor force to permit maximum use of existing capacity. Voluntary enlistments and the draft continued to make inroads among employees, but more serious was the migration to construction projects and war-production plants, which offered higher wages and less arduous work under conditions more favorable than in the mines. Turn-over increased extraordinarily, and despite widespread hiring the net number of employees continued to decline. This condition was aggravated by the enforced replacement of skilled workers with inexperienced and less competent men.[2]

In the mining of copper, which has been designated the most critical of all the war required minerals, a shortage of labor seriously threatened the attainment of production goals that in themselves scarcely met essential war needs. By that time, labor shortages had also developed in the Tri-State and western mixed-metal mines, which were attempting to increase their output of zinc, the demand for which exceeded domestic production capacity; likewise in the ferro-alloys industry the lack of manpower was causing grave apprehension, with

[2] In recognition of the pressing need for education in safety and the rapid development of efficiency in various phases of underground work, the Anaconda Copper Mining Co. initiated a training-in-work program at its Butte (Mont.) mines late in 1942. This program, the first of its kind, was described in the June 1943 issue of the Mining Congress Journal, pp. 20–27.

Digitized by Google

the situation at the world's greatest molybdenum mine especially serious. The light-metal production facilities in the West, then well on their way to completion and making an additional large drain on the labor reservoir, also experienced difficulty in obtaining an adequate labor force.

Some alleviation of the labor stringency was effected by Federal agencies. The War Manpower Commission (W. M. C.) issued a stabilization of employment order, effective September 7, 1942, in the 12 Rocky Mountain and Pacific Coast States. This order was designed to retard the outward flow of nonferrous mine workers (and those employed in the lumber industry as well) and to reduce turnover, but it did not provide for new labor supplies. Workers in these "critical" occupations were required to obtain certificates of separation from the United States Employment Service (U. S. E. S.) before seeking a job, and no employer was permitted to hire such a worker unless he furnished a certificate of separation. A liberal policy was pursued in granting these certificates, and it has been reported that only 30 percent were denied. The effectiveness of the stabilization order is said to have been sharply limited by nonobservance on the part of both workers and employers and by the lack of adequate enforcement procedure.

On September 10 National Selective Service headquarters instructed State directors to extend occupational deferment to any registrant from employment in nonferrous metal production, regardless of skill, and if any registrant left such employment to reclassify him and withdraw his designation as a "necessary man." Under these instructions Selective Service drafts declined sharply. In October, as an aid to W. M. C.'s recruitment program, authorization was given to pay transportation of western qualified workers, their families, and household goods to nonferrous mining districts, the beneficiary being required to accept employment for not less than 90 days. Incomplete returns indicate that about 4,400 men, mostly soldiers, were thus moved. In November, as a result of efforts made by W. M. C., the construction of 2,600 housing units was authorized, and actual work started within a week after the needs of each locality were determined.

Of major importance was the action of the War Department, which furloughed approximately 4,300 soldiers. Distribution to establishments that had been approved by the U. S. E. S. was made in October and November, as follows: 2,900 to copper mines, 800 to lead and zinc mines, 250 to molybdenum mines, 90 to tungsten mines, and the remainder to miscellaneous mines. The Office of Services of Supply (now the Army Service Forces) also authorized its officers to release workers employed at arsenals or other projects for mine work.

The Gold Mine Closing Order, L–208, issued by W. P. B. on October 8, 1942, displaced about 2,700 workers by the end of the year. Of these 2,100 registered with the U. S. E. S.; about 60 percent were referred to nonferrous mines and about 30 percent to other essential activities. Further incentive to employment was the War Labor Board award of October 16, increasing wages of copper, zinc, and lead workers in Utah and Idaho. The increases of 50 cents or $1 a day were conditioned upon continuity at work and upon certain productive standards. They were made retroactive to May 15 in Idaho and July 1 in Utah.

The result of these measures and those of the mine, mill, and smelter operators was a gain of roughly 5 percent in the number of employees

Digitized by Google

in the Nation's copper mines for 1941, and of 2 percent in the Mississippi Valley lead and zinc mines. In these sections of the mineral industry, some mines already had gone to a 7-day work week in 1941. The practice was considerably extended in 1942, and despite the higher rate of absenteeism that persisted throughout the year the average number of hours of employment per man for the year in the areas mentioned above rose 7 and 13 percent, respectively.

Labor shortages in the coal industry were met in part by increasing the number of operating days at the mines. A 6-day week was initiated in the soft-coal mines late in 1942 and in the anthracite mines early in 1943. Bituminous-coal mines made a 12-percent gain in production in 1942 over 1941, with a 2-percent decline in the number of workers. Pennsylvania anthracite mines increased their output by 7 percent, with a personnel 6 percent under that of 1941. An 8-percent increase in the production of coke (beehive and byproduct) was accomplished by a 5-percent increase in the number of employees at the ovens.

For the industry as a whole, an all-time record of mineral production was accomplished with 3 percent fewer employees, but the average number of hours per man rose 11 percent, and the output per man-hour—measured in value—remained close to the 1941 level.

SAFETY

Accidents to persons employed in the mineral industries were more numerous in 1942 than in 1941, and there was a slight increase in both fatality and injury rates. However, in the light of the substantial rise in accident rates experienced by industry as a whole in 1942 the safety record of the mining industry may be considered favorable. According to present reports, 1,878 deaths and 97,232 nonfatal lost-time injuries were caused by accidents in 1942, compared with 1,622 deaths and 90,334 injuries in 1941. This increase in the absolute number of accidents in 1942 was not materially out of alinement with the increased man-hours of exposure to risk. The amount of exposure to occupational hazards is measured by the number of man-days or man-hours during which the employees are at work. The weighted average of the operating time of the mineral industries during 1942, according to information available at present, was 259 days, a gain of 25 days per employee or 11 percent more than the average for 1941. Measured in man-hours, the amount of exposure to risk in 1942 was 1,550,000,000 hours, an increase of 7.6 percent. Considering the number of man-hours worked and the number of accidents, the record for 1942 shows a fatality rate of 1.20 and an injury rate of 62.72 per million man-hours of employment compared with 1.13 and 62.69, respectively, for 1941. Thus, the production record of 1942, though showing an increase in the number of accidents, was achieved without materially disturbing the number of accidents in relation to the number of man-hours worked in 1941.

Although higher accident-frequency rates were reported by some branches of the mineral industries—such as lead-zinc mines in the Mississippi Valley States, gold and silver mines, slate quarries, and smelters—lower, more favorable rates were reported for some other groups, such as copper mines, miscellaneous metal mines (a group that includes mines producing metals declared "strategic" in the conduct of the war), marble quarries, trap-rock quarries, and beehive-coke ovens.

556250—43——2

Digitized by Google

A special study of accidents to men engaged in the production of petroleum was conducted for the second consecutive year, 1942, and it revealed an accident-frequency rate of 17.97 per million man-hours of employment. This rate compares favorably with that revealed by a similar study covering 1941, which was 20.21 per million man-hours.

GOVERNMENT ORGANIZATION FOR WAR

In previous editions of Minerals Yearbook, Government organization for war insofar as it related to the mineral industries has been summarized under the heading National Defense Activity. This review carries the record forward to July 1, 1943.

The initial step toward industrial mobilization was taken on August 9, 1939, when the short-lived War Resources Board was created. In May 1940, a second step was taken with the creation of the Advisory Commission to the Council of National Defense to supervise and expedite the Nation's defense program. Eventually this commission disintegrated, and out of it emerged the Office of Production Management in January 1941 and the Office of Priec Administration and Civilian Supply in April. In August 1941 the latter became the Office of Price Administration, and its civilian-supply functions were transferred to the Office of Production Management. In addition to these agencies and the permanent Government bureaus, the following temporary organizations were in existence at the beginning of 1942 (all of them had some responsibility with regard to the production, procurement, and distribution of mineral raw materials): Office for Emergency Management, Board of Economic Warfare, Office of Scientific Research and Development, Office of Petroleum Coordinator for National Defense, Office of Solid Fuels Coordinator for War, National War Labor Board, and several subsidiaries of the Reconstruction Finance Corporation. Other agencies with functions more indirectly related to the mineral industries included: Office of Lend-Lease Administration; Office of the Coordinator of Inter-American Affairs; Supply, Priorities, and Allocations Board; Office of Defense Transportation; Office of Censorship; and others of minor significance to the mineral industries.

Reorganization and expansion of Government war administration for industry continued in 1942. In January, the War Production Board replaced the Office of Production Management and the Supply, Priorities, and Allocations Board, with Donald M. Nelson as Director replacing the dual directorship of William S. Knudsen and Sidney Hillman. In the same month a Combined Raw Materials Board was set up by the United States and Great Britain, with broad responsibility for effecting the most efficient use of the raw material resources of the two nations and for collaboration with the other United Nations along similar lines. The Reconstruction Finance Corporation, with its war subsidiaries, was transferred from the Federal Loan Agency to the direction and supervision of the Secretary of Commerce in February. April witnessed the creation of a War Manpower Commission, with Paul V. McNutt as Chairman, to establish policies and plan for the most effective use of manpower, and the delegation of broad powers to the Board of Economic Warfare in formulating policy and in directing the procurement of foreign materials for war purposes; under this authority the Board took over full responsibility for foreign purchases (except financing and warehousing) from the Reconstruc-

Digitized by Google

tion Finance Corporation in January 1943. In June 1942 the Office of War Information was set up to coordinate and determine policy for Government controls on information, and Congress passed a law creating a Smaller War Plants Corporation within the War Production Board, to insure that small business concerns will be used most efficiently and effectively in the war program.

By late summer it had become evident that more rigid control measures were required to achieve stability on the economic front. An act of October 2, 1942, passed by Congress, amended the Emergency Price Control Act of January 1942. The new act reaffirmed the existing authority of the Office of Price Administration and also authorized the President to stabilize prices, wages, and salaries affecting the cost of living. On October 3 the President delegated his powers under this statute to a Director of Economic Stabilization working through an Office of Economic Stabilization. Another outstanding development during the latter half of 1942 was the delegation of much broader powers to the Petroleum Coordinator for War and his designation as Petroleum Administrator for War.

During the first half of 1943 few changes occurred in the Government's war administration for industry. In April the Office of Solid Fuels Coordinator for War was succeeded by the Solid Fuels Administration for War. Of major significance was the establishment of an Office of War Mobilization to coordinate the Nation's war program on the industrial front, announced by the President late in May. The new agency was given full authority to determine policy and issue orders to accomplish the maximum use of the Nation's natural and industrial resources, effective use of manpower not in the armed forces, stabilization of the civilian economy, and adjustment of such economy to war needs and conditions.

Further information regarding the status and internal changes of the more important of the afore-mentioned agencies follows, and details of the action taken during 1942 are given in the commodity chapters of this volume.

Office for Emergency Management.—This is essentially an administrative agency of the Executive Office designed to maintain liaison between the President and the national war agencies and to facilitate coordination of the activities of the latter. Although many war functions have been established within the Office for Emergency Management it is essentially a clearing agency and is only remotely related to war activities in the mineral industries.

Office of War Mobilization.—The Office of War Mobilization was established within the Office for Emergency Management by Executive Order 9347 of May 27, 1943, to provide for more effective coordination of the Nation's mobilization for war. The same order also created an advisory committee composed of the Director of War Mobilization, James F. Byrnes, Chairman; the Secretaries of War and Navy; the Chairman of the Munitions Assignments Board; the Chairman of the War Production Board; and the Director of Economic Stabilization. Fred Searls is Adviser on Production to the Office of War Mobilization. The mineral industries will have little direct contact with the Office of War Mobilization but to the extent that this agency determines policies and develops programs for the maximum use of the Nation's natural and industrial resources and coordinates the activities of the action agencies, its decisions will affect mining considerably.

Digitized by Google

Office of Economic Stabilization.—This agency was created by Executive Order 9250 on October 3, 1942, to control the inflationary tendencies that had become quite acute at that time. James F. Byrnes was appointed Director of Economic Stabilization and was succeeded by Fred M. Vinson late in May 1943, when Byrnes became Director of War Mobilization. The Director of Economic Stabilization was authorized to formulate and to develop a comprehensive national economic policy relating to the control of civilian purchasing power, prices, rents, wages, salaries, profits, rationing, subsidies, and related matters for the purpose of effecting greater stability on the economic and industrial fronts. To advise the Director of Economic Stabilization, an Economic Stabilization Board was established consisting of the Director of Economic Stabilization as Chairman; the Secretaries of Treasury, Agriculture, Commerce, and Labor; the Chairman, Board of Governors, Federal Reserve System; the Director, Bureau of the Budget; the Administrator, Office of Price Administration; the Chairman, National War Labor Board; and two representatives each for labor, agriculture, and management.

War Production Board.—The War Production Board, established in January 1942 as a successor to the Office of Production Management, is the chief government agency concerned with industrial production for war, including war administration of metals and the nonmetallic minerals other than fuels. The organization of the Board, as of May 1942, was briefly described in Minerals Yearbook, 1941, but since that time many changes have been made. A major reorganization was announced by Chairman Donald M. Nelson on July 8, 1942, for the purpose of tying economic and military strategies more closely together and making more effective the Board's determination of policies and programs governing the flow of materials. William L. Batt was named Vice Chairman to serve as general assistant and deputy to Nelson. All program-development work was brought together under James S. Knowlson, who was designated a Vice Chairman for Program Determination. Other major operating units of the reorganized board included a Deputy Chairman for Program Progress (Ernest H. Kanzler) and a Director General for Operations (Amory Houghton). All industry and commodity divisions were transferred to the Director General for Operations with A. I. Henderson, formerly chief of the old Materials Division, in immediate charge as a Deputy Director General. On September 15, Kanzler succeeded Houghton, resigned, as Director General for Operations.

In September 1942 two new vice chairmen were appointed. Charles E. Wilson was designated Chairman of a new Production Executive Committee as well as Vice Chairman of the War Production Board and was assigned responsibility for seeing that programs and schedules for the war program were met. He thus became top production authority in the War Production Board. Ferdinand Eberstadt replaced Knowlson as Vice Chairman on Program Determination, was given control of the Director General for Operations, and at the same time took over the chairmanship of the War Production Board Requirements Committee. This gave him full responsibility for developing proper programs and schedules and for making materials available to meet them. Knowlson was transferred to other duties, while a new War Production Board Program Coordination Division was established under Eberstadt, with Donald D. Davis as Director. A. I.

Digitized by Google

Henderson resigned as Deputy Director General for Operations on October 31, and Knowlson resigned in January 1943.

The adoption of the Controlled Materials Plan early in November 1942 resulted in further reorganization of the War Production Board. The offices of Program Determination and Operations were consolidated under Eberstadt, with Kanzler continuing as Director General for Operations. A Program Bureau with Davis as Director and a Facilities Bureau, Fred Searls, Director, were established directly under Eberstadt. Under Kanzler four Deputy Directors General—for staff, industry divisions, field operations, and distribution—were appointed. On November 18 J. A. Krug, Deputy Director General for Distribution, announced the establishment of a Controlled Materials Plan Division, with Harold Boeschenstein as Director; he also was named Chairman of a Controlled Materials Board. At this time the industry and commodity branches, all of which had been reporting to a Deputy Director General for Industry Operations, were regrouped. The Iron and Steel, Tungsten and Molybdenum, Manganese and Chromite, and Nickel Branches were consolidated in a new Steel Division, which, together with the Copper and Aluminum-Magnesium Divisions—the three divisions coming under the Controlled Materials Plan—were placed directly under the Director General for Operations although working closely with the Controlled Materials Plan Division. The Mining, Mica-Graphite, Tin-Lead, Zinc, and Miscellaneous Minerals Branches were grouped in a Minerals Bureau under Joseph M. Scribner, Director. The Chemicals, and Cork and Asbestos Branches were merged with other industry branches in a Commodities Bureau, and the Building Materials Branch was placed in a Construction and Utilities Bureau.

The next major reorganization of the War Production Board took place early in March 1943, following the resignation of Eberstadt and the designation of Wilson as Executive Vice Chairman, with authority over all phases of War Production Board programs and activities. Meanwhile several minor changes had occurred. On November 23 an Office of Production Research and Development was established, with Harvey N. Davis as Director and C. K. Leith as Chief of its Metals and Minerals Branch. The announcement early in February of plans to coordinate and correlate the mineral programs of the various Government agencies working in this field was of particular interest to the mining industry. At that time a Mineral Resources Coordinating Division was established, which was to be aided by a Mineral Resources Operating Committee and a Minerals and Metals Advisory Committee. Howard I. Young was named Director of the new division and Chairman of the two committees. He also succeeded Scribner as Director of the Mineral Bureau.

The March 1943 reorganization was announced as a "major War Production Board shake-up." Ralph J. Cordiner, formerly Director General for War Production Scheduling, was named a Vice Chairman and special assistant to Executive Vice Chairman Wilson. Krug became Vice Chairman in charge of Materials Distribution and Chairman of the Requirements Committee, Donald D. Davis was appointed Vice Chairman for Operations, and Curtis Calder, who had succeeded Kanzler as Director General for Operations in January, was named executive assistant to Wilson.

In June 1943 two labor Vice Chairmen were named—one to handle

Digitized by Google

liaison with the War Manpower Commission and the other to have authority over labor production.

As of July 1, 1943, the members of the War Production Board and the organization units and staff dealing with policy or administration affecting the mineral industries were briefly as follows:

Members

Chairman	Donald M. Nelson
Secretary of War	Henry L. Stimson
Secretary of the Navy	Frank Knox
Secretary of Commerce	Jesse H. Jones
Secretary of Agriculture	Claude R. Wickard
Lieutenant General in Charge of War Department Production	William S. Knudsen
Administrator, Office of Price Administration	Prentiss M. Brown
Chairman, Board of Economic Warfare	Henry A. Wallace
Special Assistant to the President	Harry L. Hopkins
Chairman, War Manpower Commission	Paul V. McNutt
Director, Office of Defense Transportation	Joseph B. Eastman
Petroleum Administrator for War	Harold L. Ickes

Staff

Executive Office of the Chairman:	
Office of War Utilities, Director	J. A. Krug
Power Division, Director	B. J. Sickler
Manufactured Gas Division, Director	Alexander Macomber
Natural Gas Division, Director	Vacancy
Executive Vice Chairman	C. E. Wilson
Controller of Shipbuilding	William Francis Gibbs
Steel Division, Director	John T. Whiting
Deputy Director	Norman W. Foy
Asst. Director for Raw Materials and Facilities	Carl W. Meyers
Plant Facilities Branch, Chief	Julius A. Claus
Metallurgy and Conservation Branch, Chief	H. J. French
Raw Materials Branch, Chief	W. C. Kerber
Asst. Director for Production	J. V. Honeycutt
Asst. Director for Program and Distribution	J. L. Block
Asst. Director and Chairman Production Directive Committee	C. H. Longfield
Asst. Director for Manpower	H. J. Ruttenberg
Copper Division, Director	Harry O. King
Aluminum and Magnesium Division, Director	A. H. Bunker
Asst. Director for Ferro-Alloys	Miles K. Smith
Ferro-Alloys Branch, Chief	Andrew Leith
Program Vice Chairman	J. A. Krug
Program Bureau, Director	John F. Fennelly
Stock-Piling and Transportation Division, Director	W. Y. Elliott
Production Controls Bureau, Director	Harold Boeschenstein
Operations Vice Chairman	Donald D. Davis
Deputy Vice Chairman for Industry Operations	John J. Hall
Deputy Vice Chairman for Field Operations	Wade T. Childress
Conservation Division, Director	Howard Coonley
Salvage Division, Director	Paul C. Cabot
Redistribution Division, Director	Col. C. P. Baxter
Mineral Resources Coordinating Division, Director	Howard I. Young
Mineral Resources Operating Committee, Chairman	Howard I. Young
Representing Board of Economic Warfare	Alan Bateman
Representing Reconstruction Finance Corporation	H. DeWitt Smith
Representing Bureau of Mines	Reginald S. Dean
Representing War Production Board	Harvey N. Davis

Digitized by Google

Minerals and Metals Advisory Committee, Chairman	Howard I. Young
Lt. Col. Joseph Woodlock, War Dept.	
Lt. Com. E. H. Augustus, Navy Dept.	
Alan Bateman, Board of Economic Warfare	
Reginald S. Dean, Bureau of Mines	
H. DeWitt Smith, Reconstruction Finance Corporation.	
Donnel F. Hewett, United States Geological Survey	
Walter Janssen, Bureau of Foreign and Domestic Commerce	
Stanley B. Adams, Office of Civilian Requirements, War Production Board	
C. K. Leith, Office of Production Research and Development, War Production Board	
Ellsworth R. Bennett, Facilities Bureau, War Production Board	
Clinton Golden, Labor Production Division, War Production Board	
W. Y. Elliott, Stockpiling and Transportation Branch, War Production Board	
Minerals Bureau, Director	Howard I. Young
Mica and Graphite Division, Deputy Director	M. H. Billings
Mining Division, Director	Arthur S. Knoizen
Miscellaneous Minerals Division, Director	R. J. Lund
Tin and Lead Division, Director	Erwin Vogelsang
Zinc Division, Director	James Douglas
Commodities Bureau, Director	H. D. Hughes
Chemicals Division, Director	D. P. Morgan
Cork, Asbestos, and Fibrous Glass Division, Director	Fred W. Gardner
Consumers Goods Bureau, Director	Lewis S. Greenleaf, Jr.
Construction and Utilities Bureau, Director	James Auten
Building Materials Division, Director	John L. Haynes
Equipment Bureau, Director	Harry A. Rapelye
Vice Chairman	
Procurement Policy Division, Acting Director	Tudor Bowen
Statistics Division, Director	Stacy May
Office of Production Research and Development, Director	Harvey N. Davis
Office of Progress Reports, Director	Stacy May
Office of Special Projects, Executive Officer	A. C. C. Hill, Jr.
Facilities Bureau, Director	Charles E. Volkhardt
Facilities Division, Director	William B. Murphy
Vice Chairman for Civilian Requirements	Arthur D. Whiteside
Metals and Minerals Division, Director	S. B. Adams
Vice Chairman on Smaller War Plants	Brig. Gen. Robert W. Johnson
Vice Chairman (International Supply)	William L. Batt

Office of Price Administration.—The Emergency Price Control Act of 1942, approved by the President on January 30, 1942, created the Office of Price Administration as an independent agency with statutory authority to enforce price-control measures. Before the passage of the act it had functioned only under general executive orders. The act was amended on October 2, 1942, to extend its period of effectiveness to June 30, 1944, and to convey broader powers to the President. As previously stated, these powers were delegated to the Office of

Digitized by Google

Economic Stabilization, which thus became the agency for determining broad economic policy.

The general policy of paying subsidies for submarginal mineral production rather than stimulating output by general price increases has been continued. A General Maximum Price Regulation was issued on April 30, 1942, effective May 11, 1942, establishing maximum prices for all minerals for which ceilings previously had not been set (except "domestic ores and ore concentrates)" based on the highest price charged by seller during March 1942. The exemption of ores and concentrates had little significance because most of them were under contract to smelters under terms tied to metal prices, which were fixed, or were under contract to the Government at stipulated prices. Several revisions of the General Maximum Price Regulation were issued subsequently; details are given in the commodity chapters.

Prentiss M. Brown replaced Leon Henderson as Price Administrator in January 1943, and J. K. Galbraith resigned as Deputy Administrator of the Price Department in June 1943. As of July 1, 1943, the following units and executives of the Price Department were administering prices for minerals:

Industrial Materials Price Division:	
Director	Clair Wilcox
Office of Metal Mining Analysis, Director	Jesse L. Maury
Building Materials Branch, Price Executive	Neil Staebler
Nonferrous Metals Branch, Price Executive	John D. Sumner
Iron and Steel Branch, Price Executive	Donald D. Kennedy
Industrial Manufacturing Price Division, Director	Ben Lewis, Acting for Donald H. Wallace
Chemicals and Drugs Branch, Price Executive	Joseph D. Coppock
Fuel Price Division, Director	Sumner Pike
Petroleum Branch, Price Executive	Orville Judd
Solid Fuels Branch, Price Executive	G. G. Johnson

Board of Economic Warfare.—The most significant development in this agency in recent months, from the viewpoint of the mineral industries, was the transfer of authority and responsibility with respect to the procurement and production of imported commodities from the Reconstruction Finance Corporation to the Board of Economic Warfare. Under this arrangement, the Reconstruction Finance Corporation retained only accounting, financing, and warehousing functions in connection with purchases of foreign minerals. Further details of this transfer, as well as the Board's activities during the past year, are presented in the chapter International Aspects of War Mineral Procurement.

The foreign mineral procurement activities are largely centered in the Board's Office of Imports, under Morris Rosenthal. The technical staff of its Metals and Minerals Branch was as follows on July 1, 1943:

Acting Chief	Paul H. Nitze
Associate Chief	Alan M. Bateman
Chief Technical Consultant	Chas. W. Wright
Nonferrous Metals Division, Chief	Spencer S. Shannon
Major Base Metals Section, Chief	Raymond Brooks
Minor Base Metals Section, Chief	Neil O'Donnell
Ferro-Alloy Metals Division, Chief	Vacancy
Major Ferro-Alloys Section, Chief	Robert H. Ridgway
Minor Ferro-Alloys Section, Chief	Hugh E. McKinstry
Scrap Metals Section, Chief	Benjamin Schwartz
Industrial Minerals Division, Acting Chief	Kurt Lowenstein
Minor and Rare Metals Section, Chief	James S. Baker
Nonmetallic Minerals Section, Chief	Vacancy

Digitized by Google

Technical Services Division, Chief	Vacancy
Analysis and Reports Section, Chief	Robert K. Warner
Economics Section, Chief	John W. Evans
Mine Service and Equipment Section, Chief	C. J. Pateneaux
Foreign Plant Staff, Chief	N. S. Maddock

Petroleum Administration for War.—On May 28, 1941, the President designated the Secretary of the Interior as Petroleum Coordinator for National Defense. The designation was changed on April 20, 1942, to the Office of Petroleum Coordinator for War, and by Executive Order 9276 of December 2, 1942, this agency became the Petroleum Administration for War with the Secretary of the Interior as Administrator ex officio, directly responsible to the President. The same order greatly extended the responsibilities and powers of the Administrator to establish basic policies and formulate plans and programs to assure for the prosecution of the war the conservation and most effective development and utilization of petroleum resources in the United States and to issue necessary policy and operating orders. Formerly the Coordinator was instructed only to "make specific recommendations to appropriate departments." The Petroleum Administration for War has also been designated as Claimant Agency for the petroleum industry under the Controlled Materials Plan.

As of July 1, 1943, the organization of the Petroleum Administration for War was as follows:

Administrator—Harold L. Ickes
Deputy Administrator—Ralph H. K Davies
Assistant Deputy Administrator—R. E. Allen
Assistant Deputy Administrator—B. K. Brown
Assistant Deputy Administrator—E. L. DeGolyer
Chief Counsel—J. Howard Marshall
Executive Officer—E. L. Kohler
Director of Organizational Planning—L. S. Fish
Labor Counselor—F. H. Harbison
Production Division—Don R. Knowlton, Director
Refining Division—E. D. Cumming, Director
Transportation Division—J. R. Parten, Director
Marketing Division—Walter Hochuli
Natural Gas and Natural Gasoline Division—E. Holley Poe, Director
Foreign Division—James Terry Duce, Director
Petroleum Reserves Division—W. B. Heroy, Director
Petroleum Supply Division—Vacancy
Materials Division—Frank A. Watts, Director
Facility Security Division—A. A. Jergins, Director
Research Division—Edward B. Swanson, Director
Public Relations Division—Gordon M. Sessions, Director
Program Division—Stewart P. Coleman

Cooperation and counsel from the industry are obtained through the Petroleum Industry War Council, headed by W. R. Boyd, Jr., District Industry Committees in each of five districts into which the country has been divided, and a Foreign Operations Committee. A National Conference of State Regulatory Authorities has been organized to coordinate the activities of the State regulatory bodies governing the production of crude petroleum and natural gas, with the programs of P. A. W.; and interdepartmental committees and boards provide for clearance of matters pertaining to the activities of the various agencies of the Federal Government concerned with petroleum. Field representation of the Petroleum Administration is accomplished through five district offices, with headquarters at New York, N. Y.; Chicago, Ill.; Houston, Tex.; Denver, Colo.; and Los

Digitized by Google

Angeles, Calif. The Petroleum Administration for War also has a representative in London and through the State Department maintains petroleum attachés in various other foreign countries.

Solid Fuels Administration for War.—This agency was established within the Department of the Interior by Executive Order 9332 on April 19, 1943, to centralize the Government's policies and to broaden its activities relating to solid fuels. It succeeded the Office of Solid Fuels Coordinator for War (so designated on May 25, 1942) which had been set up as the Office of Solid Fuels Coordination for National Defense at the request of the President to the Secretary of the Interior on November 5, 1941. The Secretary of the Interior, serving ex officio as Solid Fuels Administrator, is authorized to establish policies and formulate plans and programs to assure the most effective wartime conservation, development and utilization of solid fuels, to issue necessary policy and operating orders, and to appoint any necessary industry committees or councils. He is directed to compile data and make continuing surveys of the effect of prices on solid fuels and to recommend to the O. P. A. any needed maximum price adjustments; subject to the direction of the Chairman of the War Production Board, to provide adequate supplies of solid fuels for indirect military and essential industrial and civilian requirements and to effect proper distribution of critical materials allotted to the solid-fuels industries by the War Production Board; to determine the areas and times for the rationing of solid fuels; to recommend to the Office of Defense Transportation and to the War Shipping Administration action to provide adequate transportation of solid fuels; to request action by the War Manpower Commission on manpower requirements; and to obtain from private or Government sources information, statistics, and data required to effectuate his functions.

By Executive Order 9340, issued May 1, 1943, the Secretary of the Interior took possession and control of the Nation's larger coal mines in which stoppages or strikes had occurred or were threatened. Operation of these mines was handled by the Solid Fuels Administration through an organization set up for that purpose until the establishment of a coal-mines operating organization, to which that function was transferred.

As of July 1, 1943, the organization of the Solid Fuels Administration was as follows:

Administrator—Harold L. Ickes
Deputy Administrator—Howard A. Gray
Associate Deputy Administrator—Thomas J. Thomas
Associate Deputy Administrator for Transportation—Fred A. Dawson
Assistant Deputy Administrator—Charles J. Potter
Assistant Deputy Administrator—Harlen M. Chapman
Assistant Deputy Administrator for New England—Oscar F. Ostby
Assistant Deputy Administrator at Seattle, Wash.—Vacant
Principal Assistant to the Associate Deputy Administrator—B. B. Brown
Technical Advisor—William F. Hahman
Head Conversion Engineer—Allen W. Thorson
Director, Information Division—L. W. Mosby

A Solid Fuels Advisory War Council, composed of representatives of mine producers, mine labor, coal transportation and distribution agencies, and the general public, provides cooperation and counsel. It is headed by Dr. Walter Dill Scott of Evanston, Ill., president emeritus of Northwestern University, a public representative.

Bureau of Mines.—Because of the importance of minerals in the

Digitized by Google

war program the Bureau's normal functions were quickly placed on a 100-percent war basis by a slight change in emphasis, accompanied by a substantial expansion in activity. While the Bureau had for years been conducting research on various phases of the strategic mineral problem, its present comprehensive war program was initiated following the passage of the Strategic Materials Act of 1939. At first investigations were largely restricted to the more critical materials—manganese ore, chromite, tungsten, antimony, mercury, nickel, and tin. As the defense program gained momentum this work was expanded. Simultaneously industry's demands for raw materials began reaching unprecedented proportions, causing shortages in minerals of which the Nation had enjoyed self-sufficiency for decades. Submarine warfare and shipping shortages seriously threatened imports from certain Western Hemisphere sources which had previously been considered reasonably safe, even in war. As a result of these developments, the Bureau was obliged to extend its investigation of resources to include a great variety of raw materials; many of these required technical research to develop feasible methods of beneficiation.

Early in 1943 the Director of the Bureau of Mines reported that exploratory crews were at work in 48 States and Alaska and that since the start of the work in 1939 over 92,000,000 tons of war minerals (ore) had been charted, including 35,000,000 tons of the strategic minerals previously mentioned, 46,000,000 tons of iron ore, about 5,000,000 tons of bauxite in Arkansas, 3,000,000 tons of bauxite of various grades in other areas, 2,000,000 tons of alunite, and 1,500,000 tons of magnesium ores.

In addition to its extensive program of exploration, laboratory research, and pilot-plant testing, the Bureau's work in other fields was likewise oriented to war. Economic and statistical services were expanded to meet the demands of the war agencies for more and more data on production, consumption, stocks, and sources of minerals. Helium production was rapidly increased for use in blimps, balloons, and other military and civilian uses. The Bureau's petroleum experts were busily engaged in studying the numerous problems in petroleum supply and in seeking raw materials for aviation gasoline, synthetic rubber, and high explosives. Bureau engineers were called upon to help solve coal- and coke-supply problems that threatened to slow war production, and research on production of liquid fuels from coal was speeded in preparation for possible petroleum shortages. Promotion of health and safety continued unabated, not only for the protection of the workers in the mineral industry but to keep absenteeism through accidents at a minimum at a time when manpower was scarce. Other war jobs performed by the Bureau included administration of the Explosives Control Act and inspection of mines and plants with a view to recommending precautions against sabotage and other threats to production.

The operating structure of the Bureau was decentralized into three regional units during 1942 to facilitate field operations on war projects involving exploration and metallurgical testing, which were placed under the direction of three regional engineers and a corps of 23 district engineers. The Foreign Mineral Service established in 1935 was transferred to the Department of State and converted into a Mineral Attaché Service to advise on foreign mineral problems. The Bureau

Digitized by Google

of Mines will cooperate with the new service in a consulting and supervisory capacity.

Geological Survey.—The Geological Survey staff was greatly enlarged during 1942, and its activities were almost completely diverted to war work. Its Geologic and Alaskan Branches, with the exception of the Military Geology Unit, which supplied vital information for the armed forces, were searching for war minerals in the United States, Alaska, and Latin America. Its Conservation Branch continued to administer mineral and fuel production from public lands and its expanded mapping and map-making facilities were hard-pressed to keep abreast of the enormous direct military demand for maps. The Water Resources Branch supplies data regarding water supplies for military and war-industry establishments, and several of its geologists were commissioned by the Army and assigned to solution of ground-water problems in foreign territory.

In the minerals field, stress was laid on examinations of deposits and mining properties made at the specific request of various war agencies, and more than 700 reports were transmitted to them. Geologic studies of promising regions or districts with a view toward expediting company development or production directly or toward formulating recommendations for further exploration by the Bureau of Mines or the agents of the Metals Reserve Co. were carried forward as in the previous year. To provide closer cooperation with the Bureau of Mines after its decentralization, four regional offices were established in Spokane, Salt Lake City, Rolla, and College Park. These were staffed with geologists who could be assigned to Bureau of Mines projects so as to provide geologic guidance during actual exploration and to join in the estimation of reserves. Establishment of these regional offices made no change in the Survey's basic internal organization on a commodity basis wherein groups of geologists specialize on specific mineral commodities or geologically related groups of commodities.

Investigation in Latin America in 1942 was carried on by field parties in Mexico, Cuba, Panama, Venezuela, Brazil, and Argentina.

Reconstruction Finance Corporation.—Virtually all projects for increasing the supply of minerals for war are financed through this agency or its subsidiaries. In general, the Corporation acts on the requests of the War Production Board for domestic projects and the Board of Economic Warfare for foreign projects, but it maintains close scrutiny over all proposals. The activities of the Corporation and its subsidiaries are described in the chapter on International Aspects of War Mineral Procurement.

GOVERNMENT STOCK PILES

Government purchases of minerals for stock-piling, price control, stimulation of production, preclusive buying, and other purposes continued at an accelerated rate in 1942. The wide variety of minerals and mineral products now being acquired by the Government and the extent to which the program has been expanded are indicated by the following list, which shows the items being purchased at various times:

Digitized by Google

As of end of 1941	*Added in 1942*	*Added in January–June 1943*
Aluminum (refined)	Alumina	Amblygonite
Antimony	Alumina (hydrate)	Apatite (calcium phosphates)
Asbestos	Aluminum (reclaimed)	Arsenical speiss
Bauxite	Antimony ore	Bismuth ore
Beryllium ore	Arsenic (crude)	Coal
Cadmium	Arsenic (trioxide)	Coke (petroleum)
Chromium ore	Aviation gasoline	Diamond bort
Cobalt	Baddeleyite	Emery ore (Turkish)
Copper (refined)	Beryllium oxide	Iron (pig)
Corundum ore	Bismuth	Manganese (electrolytic)
Diamonds, industrial	Carbons (Brazilian)	Mica (amber phlogopite splittings)
Graphite	Cobalt-nickel compound	Mica (amber phlogopite block)
Iridium	Cobalt oxide	Mica films
Iron ore	Columbite	Monazite sand
Kyanite	Copper (matte)	Nickel (matte content)
Lead (refined)	Copper ore	Nitrate (synthetic)
Lead ore	Corundum grain	Osmiridium
Lead vanadate concentrates	Cryolite ore	Platinum ore
Manganese ore	Ferrochromium	Tin (reclaimed)
Mercury	Ferromanganese	Tin slags
Mica	Ferrovanadium	Topaz
Nickel (refined)	Fluorspar	
Nitrate of soda	Gold ore	
Platinum	Iodine (crude)	
Quartz crystals	Iron (carbonyl)	
Rutile	Lead (bullion)	
Scrap iron	Magnesite (deadburned)	
Tin ore	Magnesium	
Tin	Manganese-iron ore	
Tungsten ore	Molybdenite	
Zinc (refined)	Nickel (copper-refinery residues)	
Zinc concentrates	Nickel (matte content)	
Zirconium ores	Osmium	
	Palladium	
	Potash (muriate)	
	Rhodium	
	Ruthenium	
	Sapphire (natural Montana)	
	Silver (foreign)	
	Slags (tantalum-columbium)	
	Spodumene	
	Strontium ores (celestite)	
	Talc (steatite)	
	Tantalite	
	Tin (cast metal)	
	Vanadium	

Many of the commodities shown are not obtained for stock-piling purposes but are purchased by the Government to centralize buying, particularly of foreign materials, to coordinate shipping, and to facilitate distribution of materials to the most essential uses. To effect the distribution of materials the War Production Board promulgated Imports Order M–63 late in December 1941; this prohibits any person, except Government agencies or their authorized representatives, from making arrangements for importing into the United States materials listed in the order, except under contracts existing at the effective date of the order or by special authorization from the War Production Board. The lists were revised several times during 1942 and at the end of the year included most of the mineral commodities being acquired by the Government.

The chief procurement agent for mineral raw materials is the Metals Reserve Co., although Defense Supplies Corporation also is an important participant in the program. Final responsibility for foreign purchases has been vested in the Board of Economic Warfare since April 1942. Details of the public purchases and stock-piling activity during 1942 are given in subsequent chapters of this volume.

STIMULATION OF DOMESTIC PRODUCTION

Several measures were adopted in 1942 to stimulate domestic production of critical minerals, all with a view to avoiding the extraordinarily high prices that prevailed during World War I, or to restrict payment of high prices to submarginal producers. A premium-price

Digitized by Google

plan for copper, lead, and zinc was announced jointly by the Office of Price Administration and the Office of Production Management (now War Production Board) in January 1942. Under the plan substantial premiums were paid over established ceiling prices for production in excess of quotas determined by a joint committee of the Office of Price Administration and the War Production Board and approved by the Metals Reserve Co. Some of the original premiums announced in January were raised in December 1942 and again in February 1943, and many quotas were revised to offset rising costs of production and to bring in additional output where possible. During 1942 premiums paid by the Government in excess of ceiling prices totaled approximately $22,500,000.

As early as 1940 the Metals Reserve Co. began contracting for large quantities of domestic ores, particularly manganese ores, guaranteeing a market for fixed tonnages at stipulated prices. This program was designed to get submarginal deposits of strategic minerals into production. However, it developed that some more flexible procedure was required to encourage small producers, so in March 1942 the company set up several buying depots where small tonnages of critical minerals would be purchased under price schedules issued from time to time. The original program has been expanded, and as of July 1943 about 30 purchase depots were operating in Arizona, Arkansas, California, Colorado, Montana, Nevada, New Hampshire, New Mexico, New York, North Carolina, Oregon, Utah, and South Dakota. Commodities purchased at these depots included chromite, manganese ores, mercury, tungsten ores, tin ores, antimony ores, vanadium ores, oxidized lead-zinc ores, beryl, molybdenum ores, mica, and columbite-tantalite ores. No one depot purchases all of these minerals, and some purchase only one or two.

Government-owned expansion of plant capacity for war mineral production is handled chiefly through the Defense Plant Corporation, which operates largely on recommendations from other war agencies charged with responsibility for administering the war program. The plants and equipment are owned by Defense Plant Corporation and operated by private industry under lease, management contract, or other arrangement. The Corporation receives rentals from the plants and in some instances has contracts for reimbursement by the war agency sponsoring the project. In the mineral field, the chief domestic commitments of this agency have been in petroleum pipe lines and in production facilities for aluminum, magnesium, steel, aviation gasoline, tin, copper, chromite, manganese ore, and zinc.

In addition to the extensive activities of its subsidiaries—Metals Reserve Co. and Defense Plant Corporation—the Reconstruction Finance Corporation has stimulated mineral production by direct loans to industry. Mining loans were liberalized considerably during 1942. In March the Corporation announced that development loans on properties that give reasonable promise of success could be obtained without mortgaging the property and could be repaid out of proceeds from production. Public Law 603, approved June 11, 1943, authorized the Corporation to make loans up to $5,000 to any one borrower for the purpose of financing the renovating, retimbering, or other preliminary development of mine workings, when such loans are deemed by the R. F. C. to be advantageous to the war program.

Prospecting and exploration assistance was given throughout the year by the Bureau of Mines and Geological Survey of the United

Digitized by Google

States Department of the Interior. Both agencies have expanded their staffs to increase war mineral production and to the extent permitted by available appropriations undertake geological investigations and exploration of ore deposits that might contribute to the war supply of minerals. In addition, the Bureau of Mines assists in determining improved methods for treating ores and in recommending to the War Production Board projects for increasing production.

Federal Aids for War Mineral Production, a pamphlet describing the various Government services for stimulating output, was issued by the War Production Board on December 15, 1942 (second edition).

INTRODUCTION

Entry into the war in December 1941 soon terminated the period of uncertainty as to the extent of this country's actual dependence on foreign sources for certain minerals. For a number of years there had been some agitation in official circles for the accumulation of mineral stock piles, but the Government took no precautionary action to anticipate inevitable shortages of many raw materials normally imported. This period ended with the enactment by Congress of the Strategic Materials Act, Public 117, 76th Congress, 1st Session, approved June 7, 1939. The purchase from abroad or from domestic sources (if available) of strategic and critical materials, as defined by the Army-Navy Munitions Board, was authorized, and $100,000,000 was to represent the total expenditure for stock piles under this act. The Procurement Division, Treasury Department, was designated as the Federal agency to purchase and stock pile the commodities specified by the Army-Navy Munitions Board. Limitations and definite restrictions in the original act retarded actual acquisition of the stock piles during the first year of operation under Public 117. The program received needed impetus in 1940 by enactment of Public 664, 76th Congress, 3d Session, approved June 25, 1940, which amended section 5 (d) of the Reconstruction Finance Corporation Act. Public 664 overshadowed Public 117 in importance. It authorized the Reconstruction Finance Corporation to organize and finance corporations "to produce, acquire, and carry strategic and critical materials as described by the President." These broad

Digitized by Google

powers of Public 664 were extended by an amendment (Public 108, 77th Cong., 1st Sess.) approved June 10, 1941. Public 108 authorized the Reconstruction Finance Corporation "to take such other action as the President and the Federal Loan Administrator may deem necessary to expedite the National Defense Program." Thus the Reconstruction Finance Corporation was provided with effective legal authority for the Government purchasing program that was in operation throughout 1942.

Under authority of Public 664, approved June 25, 1940, the Reconstruction Finance Corporation created the Metals Reserve Co., the U. S. Commercial Co., the Defense Supplies Corporation, and the Defense Plant Corporation. All of these agencies are owned, managed, and operated under supervision of the Reconstruction Finance Corporation and all have played vital roles in the acquisition of strategic and critical materials required in the conduct of the war by this country and the other United Nations.

FEDERAL AGENCIES ENGAGED IN FOREIGN MINERAL INVESTIGATIONS

METALS RESERVE COMPANY

This agency was created June 28, 1940, by the Reconstruction Finance Corporation and commenced operations with the object of building stock piles of strategic and critical metals and minerals. The program was expanded soon thereafter to include the sale of such materials when necessary in the defense program. At first, the company contracted for the purchase of materials upon a delivered basis, buying all such materials as would comply with requirements necessary to produce the required finished product. Later this program was expanded by the execution of agreements with the governments of foreign countries, particularly in South America, whereby all the exportable surplus[1] of such countries was to be sold to the Metals Reserve Co.

Between the date of its creation on June 28, 1940, and October 31, 1942, Metals Reserve Co. made commitments aggregating $3,224,348,323, of which $1,812,087,030 was for domestic activities and $1,412,261,293 for foreign transactions. Of the total commitments, $143,181,997 has been canceled, and some of the balance probably will not be used.

Antimony.—The company has contracted to purchase antimony produced in China, Mexico, Central America, and South America (chiefly Bolivia) at an approximate cost of $12,698,000. Disbursements for deliveries totaled $3,415,000 at the date of the latest company report.[2]

Chromite.—In purchasing chromite, principally for use by the steel industry in alloys, the company has contracted for production from seven countries outside the Western Hemisphere. Contracts for such production total approximately $37,665,970. In addition, contracts have been made for chromite produced in Brazil, Cuba, Alaska, and

[1] See U. S. Tariff Commission, Latin America as a Source of Strategic and Other Essential Materials, Report 144.

[2] For a complete report of this agency and other subsidiaries of the Reconstruction Finance Corporation see Report of the Reconstruction Finance Corporation, and Its Subsidiaries in Connection With the War, as of October 31, 1942.

Digitized by Google

the United States at an approximate cost of $26,774,295. Disbursements for delivery total $11,980,000.

Copper.—The company has contracted to purchase copper and copper ore, both domestic and foreign. Most of the copper and copper ore comes from other countries of the Western Hemisphere. Of the total cost of these purchases—$328,428,926—$226,203,716 has been disbursed in payment against deliveries. The copper is sold almost as rapidly as received. Defense Plant Corporation is also financing the expansion of two plants in the United States, in addition to those in Chile.

Cryolite.—The company has contracted for the purchase and importation of cryolite ore at an approximate cost of $5,308,000.

Industrial diamonds.—The company has purchased industrial diamonds from Brazil at a cost of $5,765,000. Of this amount, $4,250,000 has been disbursed for deliveries. The company has also contracted for crushing bort from other foreign countries at a cost of $2,275,000.

Graphite.—Contracts have been made for graphite from foreign countries at a cost of $5,480,000 (of which $683,000 has been disbursed), as well as for the purchase of graphite of domestic origin.

Iron ore.—The company has contracted for the purchase of domestic and Brazilian iron ore at an approximate cost of $21,896,000.

Lead.—Contracts have been made for importing refined lead from four foreign countries and ore and concentrates from seven countries at a cost of $107,497,000. Of this amount, $47,511,000 has been disbursed for deliveries.

Manganese.—Contracts have been made for imports of manganese ore from 10 foreign countries as well as for domestic ore. The amount of all contracts will aggregate approximately $149,453,000, of which $33,058,000 has been disbursed for deliveries.

Mercury.—Mercury is being purchased from Mexico, Canada, and South American countries, as well as from domestic sources. Commitments total $12,872,000, of which $7,521,000 has been disbursed.

Mica.—Mica is being purchased from four foreign countries. Purchases aggregate $9,673,000, of which $1,861,000 has been disbursed against deliveries.

Nickel.—In addition to the nickel to be produced by the facilities in Cuba financed by Defense Plant Corporation, Metals Reserve Co. has contracted for nickel and nickel-cobalt speiss for import at a cost of $8,317,000. Of this amount, $4,124,000 has been disbursed against deliveries.

Platinum.—The company has made commitments to purchase imported crude platinum at a total cost of $1,707,000. Crude platinum contains platinum, iridium, osmium, ruthenium, palladium, and gold. The company has also purchased, at a cost of $128,000, iridium produced in Russia and requisitioned by the War Department when delivered in New York.

Quartz crystals.—The company has contracted to import quartz crystals from Brazil at a cost of $7,640,000. A total of $6,929,000 has been disbursed for deliveries. Quartz crystals are necessary in radio manufacture.

Silver.—At the request of the War Production Board, and with the consent of the Secretary of the Treasury, it has been agreed to buy 10,000,000 ounces of foreign silver at 45 cents an ounce and make it available to industry under allocation by the War Production Board.

Digitized by Google

Tin.—Agreements with the International Tin Committee, starting June 28, 1940, provided for the purchase of 112,500 tons of refined tin produced in the Far East before December 31, 1941, for stock-pile purposes. In addition, the company agreed to purchase a minimum of 37,500 tons during the first 6 months of 1942, provided the International Scheme for the Regulation of Production and Export was renewed for a further term beyond December 31, 1941; the scheme, however, was not renewed. 41,596 tons of fine tin were received under this agreement, and 12,728 tons of fine tin were received in the form of tin ore for smelting in the Texas tin smelter—a total of 54,324 tons before the supply was cut off through enemy action. 11,700 tons of fine tin have been received from China and Belgian Congo. Tin ores have been received from Bolivia sufficient to manufacture 35,000 tons of fine tin, making a total already received of slightly more than 100,000 tons. A small amount has been sold.

Defense Plant Corporation constructed the Texas tin smelter at an approximate cost of $6,300,000. This smelter will produce tin both from Bolivian ores and from Far Eastern alluvial ores. When the tin smelter started operations April 5, 1942, there were in stock pile Bolivian tin ores and Netherlands East Indies ores totaling approximately a year's capacity for the smelter, which is operated for account of Metals Reserve Co.

Tungsten.—The company has contracted to purchase tungsten-containing ores from eight foreign countries and from domestic producers. Commitments for the domestic and imported ores aggregate $166,112,000, of which $19,220,000 has been disbursed.

Vanadium.—As practically all available vanadium from foreign and domestic sources is being purchased by American industry, the company has agreed to finance experimental test work for extracting vanadium from coal, crude oils, and iron ores in countries of the Western Hemisphere.

Zinc.—The company has contracted to purchase zinc and zinc ore produced in the United States and imported from eight foreign countries, at a cost of $57,748,000. Of this amount, $12,723,000 has been disbursed for deliveries.

Canadian agreement.—On June 29, 1942, the company executed an agreement with War Supplies, Ltd., a Canadian company; under its terms the company will advance (from time to time) funds not exceeding $10,000,000 to be used by the Canadian company for developing new sources of supply of copper, zinc, lead, and other strategic and critical materials and minerals required for the war effort. Under the terms of this agreement, all minerals produced from new projects developed by means of the funds advanced and also any increased production from existing projects resulting from expenditures made from such funds will be purchased by Metals Reserve Co. at cost of production and delivery. When such purchases are made, the advances for development will be amortized in the cost of the materials.

UNITED STATES COMMERCIAL COMPANY

This agency was created March 27, 1942. Its principal purpose is to compete in neutral countries, such as Spain, Turkey, and Argentina, with enemy powers for the purchase of any material that might be of use to the Axis Nations.

The company has established a working agreement with its British counterpart, the United Kingdom Commercial Corporation. The

Digitized by Google

effect of this arrangement is to enable the U. S. Commercial Co. to utilize the facilities of the British company wherever they exist. The U. S. Commercial Co. also has representatives in a number of foreign countries.

This company will sustain proportionately heavy losses.

DEFENSE SUPPLIES CORPORATION

All procurement activities involving minerals that the war requires to be financed by the Reconstruction Finance Corporation, other than those handled by Metals Reserve Co., Defense Plant Corporation, and U. S. Commercial Co., are handled by Defense Supplies Corporation. Effective July 2, 1942, the Government assumed control over virtually all imported materials by amendment to War Production Board General Preference Order M–63.

Since its creation August 29, 1940, the corporation has made commitments aggregating $3,650,725,563, of which $2,511,303,120 is for domestic and $1,139,422,443 for foreign activities. Of the total, $334,347,105 has been canceled, and much more probably will not be used. Many of these activities will involve very substantial losses. These amounts involve mineral and all other commodities and activities.

Commitments by Defense Supplies Corporation include $1,499,906,141 for the purchase of aviation gasoline and component parts and aviation-gasoline-plant expansion, essentially a domestic expenditure, and $100,000,000 to Russia for metals and other materials.

Russia.—Before lend-lease aid was extended to Russia, Defense Supplies Corporation contracted with Amtorg Trading Corporation, a United States corporation owned by Russia, to purchase needed materials from the Soviet Union to the extent of $100,000,000 and made an advance payment of $49,668,248, in the form of a loan, against delivery, subject to the condition that such advance payment be used to purchase in this country supplies needed by the Soviet Union. Materials already shipped by the Soviet Union, through Amtorg Trading Corporation, including cargoes delivered or that have been sunk, include the following mineral commodities: Asbestos, chrome ore, dead-burned magnesite, potash, and platinum.

DEFENSE PLANT CORPORATION

This agency has financed and contracted to finance the construction, equipment, partial equipment, or expansion of 1,337 plants for building or fabricating ships, bombing, fighting, transport, and cargo planes, tanks, heavy guns, ordnance, magnesium, aluminum, steel, tin, copper and other metals, synthetic rubber, high-octane aviation gasoline, machine tools, flying schools, pipe lines, etc., at an aggregate estimated cost of $8,333,839,503; by November 1942 $2,407,294,064 had been disbursed and $798,239,768 canceled. Most of this construction activity has been within the United States, but the Defense Plant Corporation is financing facilities for producing additional copper in Chile at an estimated cost of $4,999,850 and has agreed to finance another plant at an estimated cost of $15,000,000. It is also establishing facilities, at an estimated cost of $19,300,000, for producing nickel in Cuba and has authorized $4,000,000 for constructing facilities for producing vanadium in Peru.

TRANSFER OF AUTHORITY AND RESPONSIBILITY FROM RECONSTRUCTION FINANCE CORPORATION TO BOARD OF ECONOMIC WARFARE

Effective February 25, 1943, by order [3] of the Chairman, Board of Economic Warfare, the authority and functions of the four subsidiary companies of the Reconstruction Finance Corporation herein described as they pertained to imported materials, with the exception of their responsibilities relating to "the corporate execution of imported materials contracts, the disbursement of funds thereunder, the necessary accounting with respect to such disbursements, and the acceptance of delivery of commodities and materials," were transferred to the Office of Imports, Board of Economic Warfare.

BOARD OF ECONOMIC WARFARE

The genesis of the Board as it now functions may be traced to Executive Order 8839 of July 30, 1941, which established the Economic Defense Board "for the purpose of developing and coordinating policies, plans, and programs designed to protect and strengthen the international economic relations of the United States in the interest of international defense." In order to define further the functions and duties of the Economic Defense Board with respect to the unlimited national emergency as declared by the President on May 27, 1941, the following Executive orders were promulgated:

No. 8900 of September 15, 1941, transferred the duties of the Administrator of Export Control and thus amended and extended the powers of the original Executive order creating the Board.

No. 8926 of October 28, 1941, established the Lend-Lease Administration.

No. 8942 of November 19, 1941, provided for administration of the requisitioning of property required for national defense.

No. 8982 of December 17, 1941, changed the name of the Board as originally created in July 1941.

No. 9128 of April 13, 1942, defined additional duties and functions of the Economic Defense Board.

Amendment to Executive Order 9128, issued by the President on May 20, 1942, clarified and interpreted Executive Order 9128 in respect to certain functions of the United States Department of State and to relations with the Board of Economic Warfare.

Order 5, effective February 25, 1943, issued by the Vice President of the United States in his capacity of Chairman, Board of Economic Warfare, provided for additional delegations of authority to the Board and prescribed procedures and methods with respect to the procurement and production of imported commodities financed through the subsidiary companies of the Reconstruction Finance Corporation.

Attention is directed to the full texts [4] of Executive Orders 8839 of July 30, 1941; 9128 of April 13, 1942; the statement issued by the President on May 29, 1942, clarifying the relationship between the Department of State and the Board of Economic Warfare; and Order 5, effective February 25, 1943, issued by the Chairman, Board of Economic Warfare.

As a war agency the Board of Economic Warfare has been vested with broad powers and responsibilities incident to the export from this country of all commodities to foreign neutrals and allied belligerents as well as to the importation of essential raw materials from such sources. One of the principal subdivisions of the Board has as its main objectives the control and direction of commodity export movements in such a manner that the power to supply essential materials can be used as a positive economic weapon in successful prosecution of the war.

Office of Exports.—In addition to other responsibilities and with special reference to mining and related activities, the Office of Exports directs the Board's action in such a way as: To expedite the flow of raw materials required by friendly countries for the war effort either in military or civilian operations; to prevent the export of raw materials consigned to unfriendly nations or individuals; to prevent excessive depletion of stocks of essential materials in this country; and to aid in supplying machinery and other necessary equipment for development and industrial projects in friendly foreign countries where such materials are required to further the war program.

In a more positive way, the Office of Imports directs the Board's activities with respect to the mineral-procurement program.

Office of Imports.—The record of achievement in the foreign mineral program established by the Reconstruction Finance Corporation subsidiaries terminated, as already outlined, on February 25, 1943. Thereafter—except for banking and warehousing responsibilities retained by the Reconstruction Finance Corporation—the Office of Imports, Board of Economic Warfare, assumed responsibility for the negotiation, preparation, supervision, and administration, both in the United States and abroad, of all existing or future imported-materials contracts financed by the Reconstruction Finance Corporation, including development, preclusive operations, and related activities. However, all negotiations abroad are conducted in complete accordance with the provisions set forth in the statement of the President dated May 20, 1942, relating to established prerogatives of the United States Department of State.

UNITED STATES DEPARTMENT OF STATE

As the principal responsibility of the Department is to determine policies of this Government in its relation to international problems, it participates actively in the war program with respect to the procurement of essential materials from foreign countries and assumes its obvious prerogatives in connection with the longer-range postwar economic planning program.

The Executive orders heretofore mentioned, which created the several subsidiary companies of the Reconstruction Finance Corporation and the Board of Economic Warfare, provided for foreign representation of these agencies by technically trained mining experts (engineers, geologists, and ore buyers), whose duties have been confined more or less to their specialized fields. In most foreign countries where the United States has negotiated for the purchase of essential minerals (this is especially true in Latin America), preliminary transactions and final contracts with producers have been facilitated and concluded through the intermediary of some Government agency of the country involved. Thus the State Department of necessity par-

Digitized by Google

ticipated in the negotiations by procurement agencies of the United States Government whose direct responsibility has been acquisition of strategic materials. Although the Metals Reserve Co. did negotiate a 5-year contract with Bolivian tin producers in November 1940 and about the same time concluded arrangements for substantially the entire copper production of Latin America, this Government in 1941 began active negotiations with the principal American republics for over-all agreements whereby the exportable surplus of all their strategic materials would be made available to the United States. Rigid export-control systems by producing countries obviously were essential and constituted one of the principal obstacles finally surmounted in the successful negotiations of four over-all Government-to-Government agreements concluded during 1941, three of which were in operation during 1942 with Brazil, Mexico, and Chile; a Peruvian agreement expired in September 1942, and, although negotiations for a new agreement were begun later in the year, no conclusive arrangement was reached by the beginning of 1943. Separate agreements were also in effect throughout 1942 between United States Government buying agencies and individual producers of certain minerals in Argentina and Colombia.

Throughout all these negotiations, the United States Department of State maintained close contact with all agencies involved and retained its over-all responsibility for coordinating activities and efforts of the representatives of other agencies of this Government engaged in commercial or economic work within any particular country. The Bureau of Mines, by a cooperative arrangement with the State Department, provided technical assistance throughout 1942; details are covered later in this summary.

To assist the Petroleum Coordinator for War and other war agencies in collecting current information relating to the petroleum situation in key producing countries of Latin America, the State Department employed specialists and assigned them to certain American embassies.

UNITED STATES DEPARTMENT OF THE INTERIOR

Geological Survey.—The foreign work of the Survey has been confined to Latin America, where it has participated since 1940 in the cultural relations program sponsored and financed through the United States Department of State. The plans and modes of handling the projects and problems involved have been approved by that Department and the foreign governments concerned before the assignment of geologists, usually specialists in certain strategic minerals. During the fiscal year 1942 Survey geologists made detailed studies in Cuba, Mexico, and Brazil, and reconnaissance studies in Honduras and Costa Rica. During the fiscal year 1943 investigations were conducted in Cuba, Mexico, Brazil, and Central America, and additional projects were developed in Panama and Argentina. Both the War Production Board and the Board of Economic Warfare have benefited by the work of the Survey.

Bureau of Mines.—Because information regarding the mineral resources of Latin America was inadequate and urgent need for such data was anticipated, the Bureau in 1939 assigned one mining engineer to the area to collect such material. During the next 2 years comprehensive reports were compiled relating to the mineral production and trade of Bolivia, Peru, Chile, Argentina, Brazil, Uruguay, and Paraguay. During this period, officials of American embassies in the

Digitized by Google

several countries of Latin America were confronted with an ever-increasing number of problems and projects relating to mining, precipitated by the national defense program of this Government. The need for reliable technical aid to enable the several embassies to function more efficiently was evident, and the Bureau of Mines assumed responsibility for assigning mining engineers to serve as technical advisers to American embassies in Argentina, Brazil, Chile, Bolivia, Peru, and Mexico; this arrangement was in effect until July 1, 1942. The impetus of our entry into the war, with particular reference to this country's need for increased mineral supplies, resulted in the almost immediate assignment of mining engineers, geologists, and buyers throughout Latin America in particular, as well as in South Africa, Belgian Congo, and Australia, by the two agencies of this Government directly responsible for the mineral-procurement program, namely, Metals Reserve Co. and the Board of Economic Warfare. Early in 1942 the United States Department of State, empowered by special authorization to employ technical experts, created a mineral attaché service as a segment of its Auxiliary Foreign Service and on July 1, 1942, assumed administrative responsibility for the Bureau's foreign mineral specialists, who were already serving as technical advisers to our several American embassies afore-mentioned. A cooperative arrangement between the Bureau of Mines and the State Department has placed responsibility on the former for the technical supervision and direction of these mineral attachés. Coincidental with this arrangement, the Bureau has proposed for early adoption a plan whereby it will assume responsibility for more active participation in the economic studies conducted by this Government which may serve as basic data essential in the planning of international economic policy for the postwar period.

OTHER FEDERAL AGENCIES

Other than joint economic committees and raw materials boards composed of representatives of the United States and other United Nations (of which several were created during 1942 to develop maximum utilization of their combined resources in the production of war requirements), a few Federal agencies of importance in the war program were in operation during the year whose functions and responsibilities have had a direct influence on the foreign mineral investigations of those establishments afore-mentioned, although they did not participate actively in field activities.

War Production Board.—Established within the Office for Emergency Management by Executive Order 9024 of January 16, 1942, this Board has exercised direction over the entire war production and procurement program. Its recommendations have served as operating instructions covering the mineral commodities and tonnages of each to be purchased abroad and imported by the United States to insure maximum production of munitions.

Office of the Coordinator of Inter-American Affairs.—Soon after its establishment on July 30, 1941, by Executive Order 8840, this agency developed a program for assisting other American republics by providing technical aid to mining agencies of such Governments. Groups of mining engineers had been assigned to Brazil and Peru early in 1942, when the Board of Economic Warfare assumed over-all responsibility for similar activities; in consequence, these particular functions and

Digitized by Google

the personnel involved were transferred to the Board of Economic Warfare in May 1942.

Miscellaneous.—Other agencies, such as the Office of Strategic Services (a unit of the combined Chiefs of Staff, United States and Great Britain, established on February 6, 1942), the Office of Censorship, established by Executive Order 8985 of December 19, 1941, the Army-Navy Munitions Board, and the Intelligence Services of War and Navy Departments established commodity research units to analyze foreign mineral data. Major economic research and statistical agencies, such as the United States Tariff Commission and the Bureau of Foreign and Domestic Commerce, by special arrangements with the Board of Economic Warfare directed most of their activities toward meeting the requirements of the Board.

OBJECTIVES OF RESEARCH

The vast increase in the volume and character of foreign technical, economic, and statistical research relating to one phase or another of mining developed during 1942 by the Federal Government had as its preliminary objective attainment, as quickly as possible, of maximum production and procurement of the raw materials essential to the United States and other United Nations in conducting the global war against the Axis Powers. Of secondary but not minor significance is the definite need for these accumulated data in postwar economic planning programs, some ideas of which were manifest during 1942 but which early in 1943 received considerable impetus probably as a result of the military successes of the Allies in the North African and Mediterranean areas. In this connection, many plans and suggestions have been advanced that contemplate international action of one kind or another with reference to mineral production and distribution, as well as the equitable commercial and political control of mineral resources among the nations of the world. Most of the plans suggested thus far appear to stem from a desire to make effective article 4 of the Atlantic Charter, which reads—

> They will endeavor with due responsibility for their existing obligations, to further the enjoyment by all States, great or small, victor or vanquished, of access on equal terms to the trade and to the raw materials of the world which are needed for their economic prosperity.

Some ideas of the trend of thought in this direction may be gleaned from the following references:

STATISTICAL SUMMARY OF MINERAL PRODUCTION

(GENERAL UNITED STATES SUMMARY AND DETAILED PRODUCTION BY STATES)

By Martha B. Clark and Marian E. Meyer

SUMMARY OUTLINE

	Page		Page
Introduction	35	General tables	37
Unit of measurement	35	State tables	49
Elimination of duplication	35		

INTRODUCTION

This report continues the series of annual statistical summaries published in previous years as chapters of Mineral Resources and Minerals Yearbook.

UNIT OF MEASUREMENT

The unit of measurement used by the Bureau of Mines for each mineral product in reports on the mineral resources is that common to the industry concerned, and the variation in these units makes it impracticable, if not impossible, directly to combine and compare the different minerals except as to value. Although most of the products are measured by weight, some are measured by volume and some by number of "pieces," etc.; for some no total quantity figures are available.

ELIMINATION OF DUPLICATION

In the totals for the United States, shown in the following "general" tables, duplication has been eliminated wherever practicable, and in the State totals given in the State tables virtually all duplication has been eliminated. For instance, in both general and State tables the output of coke is shown but its value is not included in the totals, as the value of the coal used in its manufacture enters into the value of the coal production which is included in the totals. For asphalt, both native and oil are shown in the general tables, but the value of the oil asphalt is excluded from the totals as it duplicates that of the petroleum from which it is manufactured. For the clay industries, no figures have been available for total clay produced. For years before 1936, the total value of clay products is included in both general and State totals as representing the first marketable form of the greater part of the clay produced; the quantity and value of the clay mined and sold in the raw state by miners to users of clay are shown separately also, but the value is not included in the totals as it is duplicated largely in that for clay products. For years beginning with 1936, as the Bureau of Mines believes that a closer approach to the value of domestic clay in its first marketable form results from the inclusion of the value of clay sold by producers and of clay products other than pottery and refractories, the United States and State

Digitized by Google

totals include such values for the clay industries. This change in practice should be borne in mind when comparing the values beginning 1936 with those for earlier years.

United States totals.—In the general tables both iron ore and pig iron are shown, but the value of the pig iron rather than the iron ore is included in the United States totals, as that is considered the better means of presenting the statistics for iron in its first marketable form. For gold, silver, copper, lead, and zinc the value of "smelter output" is included in the general totals, and to account more fully for the value of the ores treated these smelter figures are supplemented by the value of the byproduct sulfuric acid. The value of pigments (white lead, red lead, lithopone, litharge, and orange mineral) manufactured from metals is not included in the general tables, as the base from which they are made is included in the output of lead or zinc, whereas the value of sublimed blue lead, sublimed white lead, leaded zinc oxide, and zinc oxide is included, as these are made in large part direct from the ores and do not enter into the lead or zinc totals, which represent smelter output.

State totals.—In the State tables also iron ore and pig iron are both shown. As blast-furnace products cannot be traced to the States in which the ore is mined, the value of the ore is used in the State totals. For ores of gold, silver, copper, lead, and zinc no values are shown, and in fact none are recorded; instead, for each of these metals the recoverable content of the ores is used as the basis of valuation. The value of the zinc and lead pigments is not included in the State total, as the recoverable zinc and lead content of the ores from which the products were made is included under zinc or lead. The value of the sulfuric acid produced as a byproduct of copper and zinc smelting and zinc roasting is not included in the State total, as tracing this product back to the State producing the ore has not been possible.

Mineral products of the United States, 1940–42—Continued

Product	1940		1941		1942	
	Quantity	Value	Quantity	Value	Quantity	Value
NONMETALLIC—continued						
Vermiculite.....short tons	22, 299	$137, 698	23, 438	$125, 444	57, 848	$319, 931
Other nonmetallic [19]		2, 806, 861		4, 457, 215		4, 257, 086
Total value of nonmetallic products (approximate)		3, 935, 300, 000		4, 746, 000, 000		5, 207, 700, 000
SUMMARY						
Total value:						
Metallic		1, 678, 600, 000		2, 132, 000, 000		2, 361, 800, 000
Nonmetallic:						
Fuels		3, 116, 500, 000		3, 708, 100, 000		4, 084, 600, 000
Other		818, 800, 000		1, 037, 900, 000		1, 123, 100, 000
Grand total approximate value of mineral products		5, 613, 900, 000		6, 878, 000, 000		7, 569, 500, 000

[1] In this general statement certain of the figures represent shipments rather than quantity mined, and some of the figures for 1942 are subject to revision. For details see following chapters of this volume.

[2] Figures withheld from publication at request of Committee for War Information.

[3] Value included in total value of metallic products.

[4] Figures represent antimonial lead produced at primary refineries from both domestic and foreign primary and secondary sources; no figures for value of antimonial lead available. Estimate of value of primary antimony and lead contents of antimonial lead from domestic sources included in total value of metallic products.

[5] Largely from foreign ore; value not included in total value.

[6] Product from domestic ores only.

[7] Value does not include premiums paid to miners by the Government. Total premiums for copper, lead, and zinc amounted to approximately $22,500,000.

[8] According to Bureau of the Mint. Valued at $35 per ounce.

[9] Value not included in total value.

[10] Value calculated at nominal price—27 cents per pound.

[11] Figures not available.

[12] Figures showing values not available.

[13] Value included in total value of metallic products; Bureau of Mines not at liberty to publish figures.

[14] According to Bureau of the Mint.

[15] Includes value of following products. Figures are shown wherever Bureau of Mines is at liberty to publish them.

1940: Bismuth, cobalt, iron ore sold for paint (9,981 short tons, $45,578), and thallium.

1941: Bismuth, cobalt, indium, iron ore sold for paint (23,287 short tons, $101,710), radium, thallium, uranium compounds; and zircon (174 short tons, $5,153).

1942: Bismuth, cobalt, germanium, indium, radium, thallium, and zircon.

[16] Value included in total value of nonmetallic products.

[17] 1940: Estimate by Bureau of Mines based on figures issued by Bureau of the Census as somewhat incomplete; 1941–42: Estimate by Bureau of Mines as no general canvass by Bureau of the Census.

[18] Includes brown coal and lignite, and anthracite mined elsewhere than in Pennsylvania.

[19] According to Bituminous Coal Division; value for bituminous includes selling expenses. Figures for 1942 are preliminary.

[20] Value included in total value of nonmetallic products; Bureau of Mines not at liberty to publish figures.

[21] No canvass. Estimate of value included in total value of nonmetallic products.

[22] Figures cover fiscal year ended June 30 of year stated.

[23] Canvass discontinued after 1915. Figures for iron ore sold for paint given in footnote 15.

[24] Sublimed blue lead, sublimed white lead, leaded zinc oxide, and zinc oxide.

[25] Equivalent as K_2O.

[26] 1940: Figures obtained through cooperation with Bureau of the Census; 1941–42: No canvass by Bureau of the Census and no estimate made.

[27] Figures for soapstone used as dimension stone included in figures for stone.

[28] From copper and zinc smelters and zinc roasters and from roasting of high-sulfide gold and silver concentrates.

[29] Includes value of following products. Figures are shown wherever Bureau of Mines is at liberty to publish them.

1940: Andalusite, crude aplite, natural sulfonated bitumen, chats (3,786,906 short tons, $572,739), dumortierite, flint lining for tube mills, pebbles for grinding, silica sand and sandstone (ground) (342,218 short tons, $2,088,314), strontium minerals (2,343 short tons, $41,442), and sulfur ore (280 long tons, $3,203).

1941: Andalusite, crude aplite, natural sulfonated bitumen, chats (5,291,491 short tons, $897,940), dumortierite, flint lining for tube mills (3,411 short tons, $54,216), pebbles for grinding (13,561 short tons, $221,826), silica sand and sandstone (ground) (487,665 short tons, $3,073,730), strontium minerals (4,724 short tons, $69,054), and sulfur ore (409 long tons, $2,553).

1942: Andalusite, crude aplite, natural sulfonated bitumen, dumortierite, flint lining for tube mills (2,576 short tons, $49,967), pebbles for grinding (15,487 short tons, $245,794), silica sand and sandstone (ground) (527,886 short tons, $3,646,643), strontium minerals (4,041 short tons, $55,529), and sulfur ore.

1938	892,600,000	2,820,300,000	650,300,000	3,470,600,000	4,363,200,000
1939	1,291,700,000	2,834,300,000	788,200,000	3,622,500,000	4,914,200,000
1940	1,678,600,000	3,116,500,000	818,800,000	3,935,300,000	5,613,900,000
1941	2,132,000,000	3,708,100,000	1,037,900,000	4,746,000,000	6,878,000,000
1942 [3]	2,361,800,000	4,084,600,000	1,123,100,000	5,207,700,000	7,569,500,000
Grand total	50,904,927,000	91,698,152,000	30,850,110,000	122,548,262,000	173,453,189,000

[1] Figures for earlier years not available.
[2] Coal, natural gas, natural gasoline and allied products, petroleum.
[3] Subject to revision.

Digitized by Google

The sum of the following State totals does not reach the total for the United States given in the preceding table partly because figures for certain of the products included in the United States total are not available by States of origin. This fact is brought out in the opening text of this chapter and in the second table following.

In addition, there are many factors (the more important discussed in the opening text) that account for the disagreement between the sum of the State totals and the grand total for the United States, by products. Chief among these are: (1) The use of iron ore values in State totals and pig iron values in United States total; (2) the use of mine figures for gold, silver, copper, lead, and zinc in the State totals and mint and smelter figures (supplemented by the value of byproduct sulfuric acid from copper and zinc smelting and zinc roasting and the value of zinc and lead pigments made in large part direct from ores) in the United States total; and (3) the inclusion of estimates in the United States total for a few products for which no canvass has been conducted for many years and for which no estimate by States is made.

Many other less important differences are involved, but both State and United States totals are as complete and definite as seems possible with the data available. The practice is consistent from year to year, and it is believed that the reader can determine readily just what minerals are covered by the total concerned.

In every table each mineral produced is listed, and all figures are shown except those that the Bureau of Mines is not at liberty to publish.

[1] In this table iron ore, not pig iron, is taken as the basis of iron valuation, and for other metals mine production (recoverable content of metals) is the basis. State totals for 1942 not yet available. Comparable totals for years before 1911 not available.

Mineral products of the United States and principal producing States in 1941

Rank in value	Product	Principal producing States [1]	
		In order of quantity	In order of value
15	Aluminum	Tennessee, New York, Washington, North Carolina	Rank same as for quantity.
101	Andalusite	California	Do.
(2)	Antimonial lead	Not separable by States	Not separable by States.
82	Antimony ore	Idaho, Nevada, Alaska, Oregon	Idaho, Alaska, Nevada, Montana.
83	Aplite (crude)	Virginia	Rank same as for quantity.
56	Arsenious oxide	Montana, Utah	Do.
61	Asbestos	Vermont, Arizona, North Carolina, Georgia	Do.
	Asphalt:		
43	Native	Texas, Oklahoma, Kentucky, Alabama	Utah, Kentucky, Oklahoma, Texas.
17	Oil	Not separable by States	Not separable by States.
44	Barite (crude)	Missouri, Tennessee, Georgia, California	Missouri, Tennessee, Georgia, Arkansas.
38	Bauxite	Arkansas, Alabama, Virginia, Georgia	Rank same as for quantity.
97	Beryllium concentrates	South Dakota, New Hampshire, Wyoming, Maine	South Dakota, Wyoming, New Hampshire, Maine.
55	Bismuth	Not separable by States	Not separable by States.
99	Bitumen (natural sulfonated)	Utah	Rank same as for quantity.
35	Boron minerals	California	Do.
28	Bromine	North Carolina, Texas, Michigan, California	Michigan, North Carolina, Texas, California.
37	Cadmium	Not separable by States	Not separable by States.
52	Calcium-magnesium chloride	Michigan, West Virginia, California, Ohio	Rank same as for quantity.
6	Cement	Pennsylvania, California, New York, Texas	Do.
59	Chats	Oklahoma, Missouri, Kansas	Missouri, Oklahoma, Kansas.
74	Chromite	California, Oregon	Rank same as for quantity.
	Clay:		
13	Products (other than pottery and refractories).		Ohio, Pennsylvania, California, New York.
25	Raw (sold by producers)	Pennsylvania, Georgia, Missouri, Ohio	Georgia, Pennsylvania, Kentucky, Missouri.
2	Coal:		
	Bituminous	West Virginia, Pennsylvania, Illinois, Kentucky	West Virginia, Pennsylvania, Kentucky, Illinois.
	Pennsylvania anthracite	Pennsylvania	Rank same as for quantity.
71	Cobalt	Pennsylvania, Vermont, Nevada	Do.
5	Coke	Pennsylvania, Ohio, Indiana, New York	Do.
8	Copper	Arizona, Utah, Montana, Nevada	Do.
46	Diatomite	California, Oregon, Nevada, Washington	Do.
102	Dumortierite	Nevada	Do.
93	Emery	New York	Do.
51	Feldspar (crude)	North Carolina, South Dakota, New Hampshire, Colorado	North Carolina, New Hampshire, South Dakota, Colorado.
10	Ferro-alloys	Pennsylvania, New York, West Virginia, Ohio	Rank same as for quantity.
92	Flint lining for tube mills	North Carolina, Minnesota, Texas, Tennessee	Minnesota, North Carolina, Texas, Tennessee.
36	Fluorspar	Kentucky, Illinois, New Mexico, Colorado	Illinois, Kentucky, New Mexico, Colorado.
49	Fuller's earth	Texas, Georgia, Florida, Illinois	Rank same as for quantity.

[1] Rank of States in metal production (except aluminum, ferro-alloys, and pig iron) arranged according to mine reports, not smelter output.
Separate figures for antimonial lead from primary sources not available.

Mineral products of the United States and principal producing States in 1941—Continued

Rank in value	Product	Principal producing States	
		In order of quantity	In order of value
72	Garnet (abrasive)	New York, North Carolina, Vermont, Idaho	New York, North Carolina, Idaho, Vermont.
(3)	Gems and precious stones	No canvass for 1941	No canvass for 1941.
9	Gold	California, Alaska, South Dakota, Colorado	Rank same as for quantity.
77	Graphite:		
	Amorphous	Nevada	Do.
	Crystalline	New York, Alabama, Georgia, Washington	Do.
66	Grindstones and pulpstones	Ohio, West Virginia, Washington	Do.
34	Gypsum (crude)	New York, Michigan, Iowa, Texas	New York, Michigan, Nevada, Iowa.
87	Helium	Texas	Rank same as for quantity.
88	Indium	Not separable by States	Not separable by States.
68	Iodine (natural)	California	Rank same as for quantity.
	Iron:		
7	Ore	Minnesota, Michigan, Alabama, Pennsylvania	Minnesota, Michigan, Alabama, New York.
3	Pig	Pennsylvania, Ohio, Indiana, Illinois	Rank same as for quantity.
53	Sinter	Tennessee	Do.
80	Kyanite	Virginia, California, North Carolina, Georgia	Virginia, North Carolina, Georgia, California.
19	Lead	Missouri, Idaho, Utah, Oklahoma	Rank same as for quantity.
21	Lime	Ohio, Pennsylvania, Missouri, West Virginia	Do.
86	Lithium minerals	South Dakota, California, North Carolina	Do.
48	Magnesite (crude)	Washington, California, Nevada, Texas	Do.
32	Magnesium	Michigan, Texas, California	Do.
41	Magnesium compounds (natural)	Michigan, Nevada, California, Texas	Michigan, California, Nevada, Texas.
47	Manganese ore	Montana, Virginia, Arkansas, Georgia	Rank same as for quantity.
40	Manganiferous ore	Minnesota, New Mexico, Nevada, Georgia	Minnesota, New Mexico, Montana, Nevada.
65	Manganiferous zinc residuum	New Jersey	Rank same as for quantity.
	Marl:		
81	Calcareous	Michigan, Indiana, Virginia, Minnesota	Michigan, North Carolina, Wisconsin, Virginia.
64	Greensand	New Jersey	Rank same as for quantity.
30	Mercury	California, Oregon, Nevada, Arkansas	Do.
58	Mica	North Carolina, Georgia, Colorado, Virginia	North Carolina, Connecticut, New Hampshire, South Dakota.
	Scrap	do	North Carolina, Georgia, Virginia, South Dakota.
	Sheet	North Carolina, New Hampshire, South Dakota, Connecticut	North Carolina, Connecticut, New Hampshire, South Dakota.
96	Millstones		North Carolina, West Virginia, New York, Virginia.
23	Mineral paints (zinc and lead pigments)	Pennsylvania, Illinois, Kansas, Ohio	Pennsylvania, Illinois, Kansas, Indiana.
(3)	Mineral waters	No canvass for 1941	No canvass for 1941.
24	Molybdenum	Colorado, Utah, New Mexico, Arizona	Rank same as for quantity.
4	Natural gas	Texas, Louisiana, California, Oklahoma	Texas, California, West Virginia, Louisiana.
14	Natural gasoline and allied products:		
	Natural gasoline and cycle products	Texas, California, Oklahoma, Louisiana	Rank same as for quantity.
	Liquefied petroleum gases	Texas, Oklahoma, California, Illinois	Texas, California, Oklahoma, West Virginia.
69	Nickel	Not separable by States	Not separable by States.
85	Oilstones, etc	Arkansas, Ohio, New Hampshire, Indiana	Rank same as for quantity.
95	Olivine	North Carolina	Do.

(4)	Ores (crude), etc.:		
	Copper	Utah, Arizona, New Mexico, Nevada	Value not available.
	Dry and siliceous (gold and silver)	Alaska, California, Nevada, South Dakota	Do.
	Lead	Missouri, Idaho, Utah, Montana	Do.
	Lead-copper	Utah, Arizona, Idaho, and Colorado and Montana	Do.
	Zinc	Oklahoma, Kansas, Tennessee, New Jersey	Do.
	Zinc-copper	Arizona	Do.
	Zinc-lead	Oklahoma, Kansas, Idaho, Missouri	Do.
	Zinc-lead-copper	Utah	Do.
63	Peat	New York, Illinois, New Jersey, Michigan	Maine, New York, Iowa, Michigan.
76	Pebbles for grinding	North Carolina, Minnesota, Texas, Wisconsin	North Carolina, Minnesota, Wisconsin, Texas.
1	Petroleum	Texas, California, Oklahoma, Illinois	Rank same as for quantity.
27	Phosphate rock	Florida, Tennessee, Montana, Idaho	Florida, Tennessee, Idaho, Montana.
60	Platinum metals	Alaska, California, Oregon, Montana	Rank same as for quantity.
26	Potassium salts	New Mexico, California, Utah, Maryland	Do.
62	Pumice	California, Kansas, Nebraska, New Mexico	California, New Mexico, Kansas, Nebraska.
50	Pyrites	Tennessee, California, Virginia, New York	Rank same as for quantity.
89	Radium	Not separable by States	Not separable by States.
22	Salt	Michigan, New York, Ohio, Louisiana	Michigan, New York, Ohio, Kansas.
12	Sand and gravel	California, New York, Michigan, Illinois	California, New York, Pennsylvania, Ohio.
57	Selenium	Not separable by States	Not separable by States.
75	Silica (quartz)	Wisconsin, North Carolina, California, Tennessee	North Carolina, Wisconsin, California, Tennessee.
45	Silica sand and sandstone (ground)	Illinois, New Jersey, Ohio, Pennsylvania	Illinois, New Jersey, Ohio, West Virginia.
20	Silver	Idaho, Montana, Utah, Arizona	Rank same as for quantity.
31	Slate		Pennsylvania, Vermont, New York, Virginia.
42	Sodium salts (carbonates and sulfates) (natural).	California, Texas, Wyoming, Utah	Rank same as for quantity.
11	Stone	Pennsylvania, Michigan, Ohio, Illinois	Pennsylvania, Ohio, New York, Illinois.
90	Strontium minerals	California, Texas, Washington	Rank same as for quantity.
18	Sulfur	Texas, Louisiana, California	Do.
33	Sulfuric acid from copper and zinc smelters and roasters and from roasting of high-sulfide gold and silver concentrates.	Pennsylvania, Illinois, Arizona, Tennessee	Pennsylvania, Illinois, Arizona, Oklahoma.
100	Sulfur ore	Texas, Nevada, Colorado	Texas, Colorado, Nevada.
39	Talc, pyrophyllite, and ground soapstone [5]	New York, North Carolina, California, Vermont	New York, California, Vermont, North Carolina.
103	Tantalite-columbite	Wyoming	Rank same as for quantity.
73	Tellurium	Not separable by States	Not separable by States.
94	Thallium	do	Do.
91	Tin	Alaska, New Mexico, Alabama, South Dakota	Rank same as for quantity.
	Titanium concentrates:		
78	Ilmenite	Virginia, Florida	Do.
67	Rutile	Virginia, Arkansas, Florida	Do.
70	Tripoli	Illinois, Missouri, Arkansas, Oklahoma	Do.
29	Tungsten ore	California, Nevada, Idaho, Colorado	California, Nevada, Colorado, Idaho.
79	Uranium compounds	Not separable by States	Not separable by States.
54	Vanadium	Colorado, Idaho, Utah, Arizona	Colorado, Utah, Idaho, Arizona.
84	Vermiculite	Montana, Wyoming, North Carolina	Rank same as for quantity.
16	Zinc	Oklahoma, New Jersey, Idaho, Kansas	Do.
98	Zircon	Florida, California	Do.

[3] No canvass for 1941. [4] Value not available. [5] Exclusive of soapstone used as dimension stone (all from Virginia), which is included in figures for stone.

States and their principal mineral products in 1941 [1]

State	Rank	Percent of total value for United States	Principal mineral products in order of value
Alabama	18	1.47	Coal, iron ore, cement, stone.
Alaska	31	.48	Gold, platinum metals, coal, silver.
Arizona	14	1.79	Copper, gold, silver, zinc.
Arkansas	25	.84	Petroleum, coal, bauxite, natural gas.
California	3	9.03	Petroleum, natural gas, gold, cement.
Colorado	20	1.32	Coal, molybdenum, gold, silver.
Connecticut	44	.09	Stone, clay products, sand and gravel, lime.
Delaware	50	.01	Clay products, stone, sand and gravel, raw clay.
District of Columbia	49	.01	Clay products.
Florida	34	.34	Phosphate rock, stone, cement, sand and gravel.
Georgia	33	.37	Raw clay, stone, cement, clay products.
Idaho	27	.81	Lead, zinc, silver, gold.
Illinois	5	5.71	Petroleum, coal, stone, cement.
Indiana	19	1.43	Coal, cement, petroleum, stone.
Iowa	29	.51	Cement, coal, stone, clay products.
Kansas	9	3.06	Petroleum, natural gas, zinc, coal.
Kentucky	10	3.01	Coal, natural gas, petroleum, stone.
Louisiana	7	4.07	Petroleum, natural gas, sulfur, natural gasoline.
Maine	45	.08	Stone, cement, sand and gravel, slate.
Maryland	37	.31	Sand and gravel, coal, cement, stone.
Massachusetts	40	.17	Stone, sand and gravel, clay products, lime.
Michigan	12	2.54	Iron ore, petroleum, cement, salt.
Minnesota	8	3.18	Iron ore, manganiferous ore, sand and gravel, stone.
Mississippi	36	.32	Petroleum, sand and gravel, natural gas, clay products.
Missouri	22	1.10	Lead, cement, stone, coal.
Montana	17	1.54	Copper, zinc, silver, gold.
Nebraska	43	.12	Cement, petroleum, sand and gravel, stone.
Nevada	26	.83	Copper, gold, silver, tungsten ore.
New Hampshire	47	.02	Clay products, stone, sand and gravel, feldspar.
New Jersey	28	.70	Zinc, clay products, sand and gravel, stone.
New Mexico	15	1.74	Petroleum, copper, potassium salts, natural gas.
New York	16	1.63	Cement, petroleum, stone, sand and gravel.
North Carolina	35	.34	Clay products, stone, bromine, sand and gravel.
North Dakota	46	.06	Coal, sand and gravel, clay products, stone.
Ohio	11	2.94	Coal, clay products, natural gas, lime.
Oklahoma	6	4.70	Petroleum, natural gas, zinc, natural gasoline.
Oregon	39	.23	Gold, stone, cement, sand and gravel.
Pennsylvania	2	13.13	Coal, cement, natural gas, petroleum.
Rhode Island	48	.02	Stone, sand and gravel, clay products, lime.
South Carolina	42	.13	Stone, clay products, raw clay, sand and gravel.
South Dakota	32	.44	Gold, stone, cement, sand and gravel.
Tennessee	23	1.00	Coal, stone, cement, zinc.
Texas	1	15.46	Petroleum, natural gas, sulfur, natural gasoline.
Utah	13	2.18	Copper, gold, coal, silver.
Vermont	41	.14	Stone, slate, talc, asbestos.
Virginia	21	1.27	Coal, stone, sand and gravel, cement.
Washington	30	.51	Coal, cement, gold, sand and gravel.
West Virginia	4	7.58	Coal, natural gas, petroleum, stone.
Wisconsin	38	.30	Stone, iron ore, sand and gravel, cement.
Wyoming	24	.94	Petroleum, coal, natural gas, natural gasoline.

[1] In this table iron ore, not pig iron, is taken as the basis of iron valuation, and for other metals mine production (recoverable content of metals) is the basis.

Prices of gold, silver, copper, lead, and zinc, 1932–42 [1]

Year	Gold [2]	Silver [3]	Copper [4]	Lead [4]	Zinc [4]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1932	[5] $20.67+	$0.282	$0.063	$0.030	$0.030
1933	25.56	.350	.064	.037	.042
1934	34.95	[6] .646+	.080	.037	.043
1935	35.00	.71875	.083	.040	.044
1936	35.00	.7745	.092	.046	.050
1937	35.00	.7735	.121	.059	.065
1938	35.00	[6] .646+	.098	.046	.048
1939	35.00	[7] .678+	.104	.047	.052
1940	35.00	[8] .711+	.113	.050	.063
1941	35.00	[8] .711+	.118	.057	.075
1942	35.00	[8] .711+	.121	.067	.093

[1] Treasury legal coinage value of gold from Jan. 18, 1837, to Jan. 31, 1934, was $20.67+ per fine ounce. For table of prices for silver, copper, lead, and zinc from 1850 to 1931, by years, see Mineral Resources, 1931, pt. 1, p. A115.

[2] 1932: Legal coinage value; 1933–34: Yearly average weighted Government price; 1935–42: Price under authority of Gold Reserve Act of January 31, 1934.

[3] 1932–33: Average New York price for bar silver; 1934 and 1939–42: Treasury buying price for newly mined silver; 1935–37: Yearly average weighted Treasury buying price for newly mined silver.

[4] Yearly average weighted price of all grades of primary metal sold by producers.

[5] $20.671835. [6] $0.64646464. [7] $0.67878787. [8] $0.71111111.

STATE TABLES

Mineral production of Alabama, 1940–41

Product	1940		1941	
	Quantity	Value	Quantity	Value
Aluminum.....short tons	----------	----------	([1] [2])	([1] [2])
Asphalt (native).....do	([1])	([1])	([1])	([1])
Bauxite.....do	([1])	([1])	([1])	([1])
Cement.....barrels	[3] 5, 249, 759	[3] $7, 617, 405	[3] 7, 610, 030	[3] $11, 142, 649
Clay:				
Products (other than pottery and refractories)	----------	[4] 2, 394, 000	----------	[4] 2, 647, 000
Raw (sold by producers).....short tons	144, 354	143, 363	179, 023	186, 476
Coal.....do	[5] 15, 324, 163	[5] 35, 777, 923	[5] 15, 464, 523	[5] 41, 985, 942
Coke.....do	4, 727, 378	[3] 13, 748, 837	4, 855, 062	[3] 18, 628, 534
Ferro-alloys.....do	45, 184	[3] 3, 422, 111	([1] [2])	([1] [2])
Gold.....troy ounces	5	175	30	1, 050
Graphite, crystalline.....pounds	----------	----------	([1])	([1])
Iron:				
Ore.....short tons	8, 210, 061	12, 606, 369	8, 818, 015	18, 090, 992
Pig.....do	3, 476, 072	[3] 49, 706, 851	3, 712, 018	[3] 64, 037, 109
Lime.....do	234, 147	1, 359, 371	306, 836	1, 705, 558
Manganese ore.....do	272	([1])	([1])	([1])
Manganiferous ore.....do	383	([1])	----------	----------
Mica:				
Scrap.....short tons	([1])	([1])	([1])	([1])
Sheet.....pounds	([1])	([1])	([1])	([1])
Mineral waters.....gallons sold	([6])	([6])	([6])	([6])
Ore (dry and siliceous) (gold and silver).short tons	900	([7])	1, 020	([7])
Sand and gravel.....do	1, 840, 945	936, 724	2, 428, 995	1, 556, 457
Silver.....troy ounces	3	2	3	2
Stone.....short tons	2, 496, 480	3, 048, 043	2, 804, 740	3, 745, 651
Tin (metallic equivalent).....do	----------	----------	([1])	([1])
Miscellaneous [8]	----------	1, 114, 643	----------	8, 468, 526
Total value, eliminating duplications	----------	64, 998, 018	----------	82, 730, 210

[1] Value included under "Miscellaneous."
[2] Value not included in total value for State.
[3] Exclusive of puzzolan, value for which is included under "Miscellaneous."
[4] 1940: Estimate by Bureau of Mines based on figures issued by Bureau of the Census as somewhat incomplete; 1941: Estimate by Bureau of Mines as no general canvass by Bureau of the Census.
[5] According to Bituminous Coal Division; value includes selling expenses.
[6] No canvass.
[7] Not valued as ore; value of recoverable metal content included under the metals.
[8] Includes minerals indicated by "[1]" and "[2]" above.

Mineral production of Alaska, 1940–41

Product	1940		1941	
	Quantity	Value	Quantity	Value
Antimony ore (concentrates).....short tons	([1])	([1])	([1])	([1])
Arsenic.....do	([2])	([2])	([2])	([2])
Coal.....do	[3] 173, 970	[3] $695, 000	[4] 238, 960	[4] $944, 588
Copper.....pounds	110, 000	12, 430	144, 000	16, 992
Gold.....troy ounces	755, 970	26, 458, 950	695, 467	24, 341, 345
Lead.....short tons	779	77, 900	662	75, 468
Mercury.....flasks (76 pounds)	162	28, 653	([1])	([1])
Ores (crude), etc.:				
Copper.....short tons	----------	----------	144	([5])
Dry and siliceous (gold and silver).....do	4, 885, 023	([5])	4, 480, 364	([5])
Platinum metals (crude).....troy ounces	32, 300	1, 093, 000	([1])	([1])
Sand and gravel.....short tons	515, 011	103, 217	[6] 530, 997	[6] 87, 116
Silver.....troy ounces	191, 679	136, 305	191, 522	136, 193
Stone.....short tons	([1])	([1])	----------	----------
Tin (metallic equivalent).....do	52	52, 000	([1])	([1])
Miscellaneous [7]	----------	66, 766	----------	1, 207, 678
Total value, eliminating duplications	----------	28, 724, 221	----------	26, 809, 380

[1] Value included under "Miscellaneous."
[2] Figures not available.
[3] According to the Alaskan Branch of the Geological Survey.
[4] According to Bituminous Coal Division; value includes selling expenses.
[5] Not valued as ore; value of recoverable metal content included under the metals.
[6] "Government-and-contractor." Value of "Commercial" included under "Miscellaneous."
[7] Includes minerals indicated by "[1]" and "[6]" above.

Mineral production of California, 1940–41—Continued

Product	1940		1941	
	Quantity	Value	Quantity	Value
Natural gasoline and allied products:				
Natural gasoline ..... gallons	587,476,000	$27,901,000	577,127,000	$24,067,000
Liquefied petroleum gases ..... do	(2)	(2)	82,638,000	2,082,000
Ores (crude), etc.:				
Copper ..... short tons	446,392	(6)	292,232	(6)
Dry and siliceous (gold and silver) ..... do	4,214,650	(6)	3,968,283	(6)
Lead ..... do	8,199	(6)	18,338	(6)
Lead-copper ..... do	11	(6)	2	(6)
Zinc ..... do	----------	----------	1,330	(6)
Zinc-lead ..... do	181	(6)	----------	----------
Peat ..... do	4,116	21,110	3,618	17,898
Pebbles for grinding ..... do	(1)	(1)	574	2,856
Petroleum ..... barrels	223,881,000	216,720,000	230,263,000	239,500,000
Platinum metals (crude) ..... troy ounces	1,400	(1)	(1)	(1)
Potassium salts ..... short tons	(1)	(1)	(1)	(1)
Pumice ..... do	32,123	152,885	77,951	268,734
Pyrites ..... long tons	(1)	(1)	(1)	(1)
Salt (sodium chloride) ..... short tons	469,354	2,200,640	484,632	2,290,265
Sand and gravel ..... do	18,913,301	8,988,894	7 19,617,609	7 10,988,766
Sand and sandstone (ground) ..... do	5,505	39,080	(1)	(1)
Silica (quartz) ..... do	(1)	(1)	2,526	36,721
Silver ..... troy ounces	2,359,776	1,678,063	2,154,188	1,531,867
Slate	----------	(1)	----------	53,765
Sodium salts (carbonates and sulfates) (natural) ..... short tons	233,590	2,183,110	218,903	2,224,084
Stone ..... do	6,340,080	5,048,242	8 9,139,390	8 7,535,017
Strontium minerals ..... do	287	4,282	(1)	(1)
Sulfur ..... long tons	(1)	(1)	8,803	139,800
Sulfuric acid 9 ..... short tons	(1 5)	(1 5)	(1 5)	(1 5)
Talc and ground soapstone ..... do	36,282	476,926	59,203	811,793
Tripoli ..... do	(1)	(1)	(1)	(1)
Tungsten ore (60-percent concentrates) ..... do	2,070	2,561,042	(1)	(1)
Zinc ..... do	79	9,954	440	66,000
Zircon ..... do	----------	----------	30	545
Miscellaneous 10	----------	8,155,536	----------	20,707,659
Total value, eliminating duplications	----------	455,672,038	----------	506,795,395

1 Value included under "Miscellaneous."
2 Figures not available.
3 1940: Estimate by Bureau of Mines based on figures issued by Bureau of the Census as somewhat incomplete; 1941: Estimate by Bureau of Mines as no general canvass by Bureau of the Census.
4 No canvass.
5 Value not included in total value for State.
6 Not valued as ore; value of recoverable metal content included under the metals.
7 "Commercial." Value of "Government-and-contractor" included under "Miscellaneous."
8 Exclusive of dimension unclassified stone, value for which is included under "Miscellaneous."
9 From roasting of high-sulfide gold and silver concentrates.
10 Includes minerals indicated by "1," "7," and "8" above.

Mineral production of Colorado, 1940–41

Product	1940		1941

Manganiferous ore	short tons	20,851	[2]		
Marl, calcareous	do	[2]	[2]	66,854	35,684
Mineral waters	gallons sold	[5]	[5]	[5]	[5]
Natural gas	M cubic feet	12,648,000	8,339,000	13,916,000	8,722,000
Natural gasoline	gallons	3,919,000	162,000	5,670,000	261,000
Ores (crude), etc.: Copper	short tons	4,438,219	[6]	4,282,448	[6]
Peat	do	5,326	32,750	11,340	75,500
Petroleum	barrels	19,753,000	20,150,000	16,359,000	21,900,000
Salt	short tons	2,863,035	7,479,905	3,620,649	10,975,872
Sand and gravel	do	13,650,528	4,978,006	15,606,215	6,190,336
Sand-lime brick	thousands of brick	[7] 14,564	[7] 170,678	[7]	[7]
Silver	troy ounces	88,657	63,045	60,796	43,233
Stone	short tons	13,527,170	6,891,433	15,161,820	8,349,607
Miscellaneous [8]			1,891,690		6,780,873
Total value, eliminating duplications			124,774,581		142,433,673

[1] 1940: Estimate by Bureau of Mines based on figures issued by Bureau of the Census as somewhat incomplete; 1941: Estimate by Bureau of Mines as no general canvass by Bureau of the Census.
[2] Value included under "Miscellaneous."
[3] According to Bituminous Coal Division; value includes selling expenses.
[4] Value not included in total value for State.
[5] No canvass.
[6] Not valued as ore; value of recoverable metal content included under the metals.
[7] 1940: Figures obtained through cooperation with Bureau of the Census; 1941: No canvass by Bureau of the Census and no estimate made.
[8] Includes minerals indicated by "2" above.

Mineral production of Minnesota, 1940–41

Product		1940		1941	
		Quantity	Value	Quantity	Value
Cement	barrels	(1)	(1)	(1)	(1)
Clay:					
Products (other than pottery and refractories)			[2] $988,116		[2] $1,119,000
Raw (sold by producers)	short tons	(1)	(1)	(1)	(1)
Coke	do	524,360	[3] 3,662,908	685,873	[3] 5,082,787
Ferro-alloys	do			(1 3)	(1 3)
Flint lining for tube mills	do	(1)	(1)	(1)	(1)
Gems and precious stones			[4]		[4]
Iron:					
Ore	short tons	53,652,633	118,947,968	70,419,878	167,781,967
Pig	do	282,728	(1 3)	369,549	(1 3)
Lime	do	(1)	(1)	(1)	(1)
Manganiferous ore	do	1,171,939	2,894,388	(1)	(1)
Marl, calcareous	do	(1)	(1)	21,387	11,664
Mineral waters	gallons sold	[4]	[4]	[4]	[4]
Peat	short tons	1,984	19,980	(1)	(1)
Pebbles for grinding	do	(1)	(1)	(1)	(1)

Mineral production of Montana, 1940–41

Product	1940		1941	
	Quantity	Value	Quantity	Value
Antimony ore (concentrates)—short tons	69	$3,000	[1]	[1]
Arsenious oxide—do	[1]	[1]	[1]	[1]
Asbestos—do	[1]	[1]		
Bismuth—pounds	[2]	[2]	[2]	[2]
Cement—barrels	[1]	[1]	[1]	[1]
Clay:				
Products (other than pottery and refractories)		[3] 155,000		[3] $231,000
Raw (sold by producers)—short tons	[1]	[1]	[1]	[1]
Coal:				
Bituminous—do	[4] 2,818,936	[4] 4,075,528	[4] 3,194,931	[4] 4,725,392
Lignite—do	48,264	86,000	58,793	105,000
Copper—pounds	252,782,000	28,564,366	256,072,000	30,216,496
Gems and precious stones		[5]		[5]
Gold—troy ounces	272,602	9,541,070	246,475	8,626,625
Graphite, crystalline—pounds			[1]	[1]
Gypsum (crude)—short tons	[1]	[1]	[1]	[1]
Lead—do	23,036	2,303,600	21,259	2,423,526
Lime—do	18,797	77,658	[1]	[1]
Manganese ore—do	21,664	[1]	[1]	[1]
Manganiferous ore—do	4,051	[1]	[1]	[1]
Mineral waters—gallons sold	[5]	[5]	[5]	[5]
Natural gas—M cubic feet	26,231,000	7,132,000	28,499,000	7,597,000
Natural gasoline and allied products:				
Natural gasoline—gallons	2,603,000	162,000	2,517,000	177,000
Liquefied petroleum gases—do	[2]	[2]	1,449,000	81,000
Ores (crude), etc.:				
Copper—short tons	3,287,803	[6]	3,791,202	[6]
Dry and siliceous (gold and silver)—do	1,028,523	[6]	940,067	[6]
Lead—do	29,454	[6]	33,029	[6]
Lead-copper—do	71	[6]	4	[6]
Zinc—do	174,181	[6]	182,745	[6]
Zinc-lead—do	579,209	[6]	695,202	[6]
Petroleum—barrels	6,728,000	6,660,000	7,526,000	8,000,000
Phosphate rock—long tons	64,239	184,844	105,108	318,588
Platinum metals (crude)—troy ounces	31	[1]	[1]	[1]
Pyrites—long tons	[1]	[1]	[1]	[1]
Sand and gravel—short tons	4,978,353	1,953,009	4,706,685	1,871,912
Silver—troy ounces	12,361,050	8,790,080	12,386,925	8,808,480
Stone—short tons	829,600	813,286	455,680	336,632
Talc—do			[1]	[1]
Tin (metallic equivalent)—pounds	[1]	[1]	[1]	[1]
Tungsten ore (60-percent concentrates)—short tons	50	[1]	[1]	[1]
Vermiculite—do	[1]	[1]	[1]	[1]
Zinc—do	52,587	6,625,962	60,710	9,106,500
Miscellaneous [7]		2,360,470		3,958,309
Total value, eliminating duplications		79,487,873		86,583,460

[1] Value included under "Miscellaneous."
[2] Figures not available.
[3] 1940: Estimate by Bureau of Mines based on figures issued by Bureau of the Census as somewhat incomplete; 1941: Estimate by Bureau of Mines as no general canvass by Bureau of the Census.
[4] According to Bituminous Coal Division; value includes selling expenses.
[5] No canvass.
[6] Not valued as ore; value of recoverable metal content included under the metals.
[7] Includes minerals indicated by "1" above.

Mineral production of Nebraska, 1940–41

Product	1940		1941	
	Quantity	Value	Quantity	Value
Cement—barrels	[1]	[1]	[1]	[1]
Clay:				
Products (other than pottery and refractories)		[2] $412,000		[2] $659,000
Raw (sold by producers)—short tons	10,417	5,781	11,969	6,048
Mineral waters—gallons sold	[3]	[3]	[3]	[3]
Petroleum—barrels	276,000	220,000	1,898,000	1,600,000
Pumice—short tons	[1]	[1]	7,512	54,513
Sand and gravel—do	3,051,706	1,072,935	3,176,701	1,273,066
Stone—do	832,890	906,563	[4] 328,690	[4] 660,573
Miscellaneous [5]		2,074,867		2,245,870
Total value, eliminating duplications		4,692,146		6,499,070

[1] Value included under "Miscellaneous."
[2] 1940: Estimate by Bureau of Mines based on figures issued by Bureau of the Census as somewhat incomplete; 1941: Estimate by Bureau of Mines as no general canvass by Bureau of the Census.
[3] No canvass.
[4] Exclusive of dimension limestone, value for which is included under "Miscellaneous."
[5] Includes minerals indicated by "1" and "4" above.

[4] No canvass.
[5] Not valued as ore; value of recoverable metal content included under the metal.
[6] 1940: Figures obtained through cooperation with Bureau of the Census; 1941: No canvass by Bureau of the Census and no estimate made.
[7] Value reported for zinc in New Jersey is estimated smelting value of recoverable zinc content of ore after freight, haulage, smelting, and manufacturing charges are added.
[8] Includes minerals indicated by "[1]" above.

Mineral production of New Mexico, 1940–41

Product	1940		1941	
	Quantity	Value	Quantity	Value
Arsenious oxide.....short tons	(1)	(1)	(1)	(1)

Mineral production of Utah, 1940–41—Continued

Product	1940		1941	
	Quantity	Value	Quantity	Value
Mercury.....flasks (76 pounds)..	53	$9,374	(1)	(1)
Molybdenum.....pounds..	4,285,688	(1)	(1)	(1)
Natural gas.....M cubic feet..	5,124,000	1,063,000	5,562,000	$1,145,000
Natural gasoline.....gallons..	722,000	28,000	808,000	45,000
Ores (crude), etc.:				
Copper.....short tons..	26,301,745	(7)	30,444,402	(7)
Dry and siliceous (gold and silver).....do....	795,123	(7)	622,650	(7)
Lead.....do....	65,072	(7)	77,979	(7)
Lead-copper.....do....	8,510	(7)	5,276	(7)
Zinc.....do....	26	(7)	2,302	(7)
Zinc-lead.....do....	768,870	(7)	798,864	(7)
Zinc-lead-copper.....do....			1,344	(7)
Petroleum.....barrels..	3,000	3,000	4,000	4,000
Phosphate rock.....long tons..	----------	----------	1,340	8,535
Potassium salts.....short tons..	(1)	(1)	(1)	(1)
Salt (sodium chloride).....do....	71,472	191,263	107,079	196,413
Sand and gravel.....do....	1,899,563	582,708	2,760,025	935,371
Silver.....troy ounces..	12,172,299	8,655,857	11,395,485	8,103,456
Sodium sulfate (natural).....short tons..	(1)	(1)	(1)	(1)
Stone.....do....	1,024,660	693,127	408,140	340,551
Sulfur.....long tons..	(1)	(1)	----------	----------
Sulfuric acid [5].....short tons..	(1 6)	(1 6)	(1 5)	(1 6)
Tungsten ore (60-percent concentrates).....do....	14	(1)	(1)	(1)
Vanadium.....pounds..	160,912	(1)	(1)	(1)
Zinc.....short tons..	43,788	5,517,288	42,049	6,307,350
Miscellaneous [8].....	----------	10,431,709	----------	16,096,221
Total value, eliminating duplications.....	----------	104,392,989	----------	122,386,473

[1] Value included under "Miscellaneous."
[2] Figures not available.
[3] 1940: Figures obtained through cooperation with Bureau of the Census; 1941: Estimate by Bureau of Mines as no general canvass by Bureau of the Census.
[4] According to Bituminous Coal Division; value includes selling expenses.
[5] Value not included in total value for State.
[6] No canvass.
[7] Not valued as ore; value of recoverable metal content included under the metals.
[8] From copper smelting.
[9] Includes minerals indicated by "1" above.

Mineral production of Vermont, 1940–41

Product	1940		1941	
	Quantity	Value	Quantity	Value
Asbestos.....short tons..	(1)	(1)	(1)	(1)
Clay:				
Products (other than pottery and refractories)...	----------	(1 2)	----------	(1 2)
Raw (sold by producers).....short tons..	(1)	(1)	(1)	(1)
Cobalt.....pounds..	----------	----------	1,399	(1)
Garnet, abrasive.....short tons..	(1)	(1)	(1)	(1)
Lime.....do....	61,026	$430,178	67,824	$479,219
Mica, scrap.....do....	290	2,964	(1)	(1)
Mineral waters.....gallons sold..	(3)	(3)	(3)	(3)
Nickel.....short tons..	----------	----------	(1)	(1)
Sand and gravel.....do....	4 873,325	4 217,661	4 601,918	4 127,149
Slate.....	----------	1,555,230	----------	1,921,923
Stone.....short tons..	5 135,680	5 3,681,752	185,840	4,190,112
Talc.....do....	38,516	423,368	57,248	663,468
Miscellaneous [6].....	----------	668,619	----------	749,799
Total value, eliminating duplications.....	----------	6,979,772	----------	8,131,670

[1] Value included under "Miscellaneous."
[2] 1940: Figures obtained through cooperation with Bureau of the Census; 1941: Estimate by Bureau of Mines as no general canvass by Bureau of the Census.
[3] No canvass.
[4] "Government-and-contractor." Value of "Commercial" included under "Miscellaneous."
[5] Exclusive of crushed sandstone, value for which is included under "Miscellaneous."
[6] Includes minerals indicated by "1," "4," and "5" above.

GENERAL SUMMARY

Gold and silver, beset by regulations, labor shortages, and economic factors, made a poor showing in many countries in 1942, and output in the United States dropped to the lowest quantity since 1935. World production of gold slumped an estimated 10 percent and silver about 5 percent from 1941, although information from many foreign countries on both metals is so scanty that many estimates have little value. Output of gold in North America declined about 16 percent. Production in the United States was reduced 26 percent, Canada 10 percent, and Newfoundland 26 percent; Mexico, however, reported a very slight increase. South America recorded a decrease of about 10 percent. The world's greatest gold-producing nation, the Union of South Africa, maintained its production at a high figure in spite of difficulties, and output decreased only about 2 percent.

Silver output in the United States dropped less in proportion than gold but dropped 21 percent from 1941. The increased tonnage of base-metal ores maintained production of silver better than of gold. Production in Canada held up well, and output differed but little from 1941; in Mexico it increased over 8 percent and climbed to the highest figure since 1931. Production in Central and South America remained much as in 1941; in fact, South America is believed to have made a slight increase. Output in the Western Hemisphere as a whole decreased about 5 percent.

GOVERNMENT REGULATIONS AND THEIR EFFECTS

Gold.—The marked slump in gold output in the United States in 1942 was traceable to the effects of the war program. Even as early as 1941, labor began to leave the mines to seek higher wages in defense industries, and the movement became much more pronounced in 1942. Another factor in the decreased production was the order from the War Production Board early in 1942 that excluded gold and silver mines from the priority benefits of Preference Rating Order P–56. Thus, shortages of labor and equipment, coupled with increased taxes and fixed prices for gold and silver, were already rapidly forcing down production late in 1941 and early in 1942.

On October 8, 1942, the War Production Board issued its Limitation Order L–208, the essential part of which reads as follows:

(a) *Definitions.*—For the purposes of this order (1) "Nonessential mine" means any mining enterprise in which gold is produced, whether lode or placer, located

Digitized by Google

in the United States, its Territories or possessions, unless the operator of such mining enterprise is the holder of a serial number for such enterprise which has been issued under Preference Rating Order P–56.

(2) With respect to any nonessential mine, "effective date" means October 8, 1942, or the date of cancellation by the Director General for Operations of the serial number for such mining enterprise, whichever is the later.

(b) *Restrictions upon production.*—(1) On and after the effective date, each operator of a nonessential mine shall immediately take all such steps as may be necessary to close down, and shall close down, in the shortest possible time, the operations of such mine.

(2) In no event on or after seven days from the effective date shall any operator of a nonessential mine acquire, consume, or use any material, facility, or equipment to break any new ore or to proceed with any development work or any new operations in or about such mine.

(3) In no event on or after sixty days from the effective date shall any operator of a nonessential mine acquire, consume, or use any material, facility, or equipment to remove any ore or waste from such mine, either above or below ground, or to conduct any other operations in or about such mine, except to the minimum amount necessary to maintain its buildings, machinery, and equipment in repair and its access and development workings safe and accessible.

(4) The provisions of this order shall not apply to any lode mine which produced 1,200 tons or less of commercial ore in the year 1941, provided the rate of production of such mine, after the effective date, shall not exceed 100 tons per month, nor to any placer mine which treated less than 1,000 cubic yards of material in the year 1941, provided that the rate of treatment of such placer mine, after the effective date, shall not exceed 100 cubic yards per month.

The Board also asked the mines affected to submit complete data covering the minimum number of workers and the minimum quantity of critical materials needed to keep the mines on a basis sufficient to pay stand-by expenses, together with information on the ages of employees and whether stand-by operations could be maintained with men above military age.

On November 25, Order L–208 was amended so that equipment of types listed on Schedule A, Order P–56, could no longer be sold without permission from the War Production Board, and the equipment was to be inventoried and reported by January 15, 1943, or within 60 days after revocation of a P–56 serial number. The lists submitted were to indicate the prices of machinery that the owner was willing to sell or rent so that the Board could distribute the available units to other mines where the output of needed metals could be considerably increased.

On December 8 the Board announced that regulations had been eased slightly so that a number of mines were granted permission to remove and mill broken ore or gravel with a small crew of men for 6 months, provided that such operations would not consume substantial amounts of critical materials and would employ only men who were not eligible for military service or not needed in mining operations elsewhere.

The avowed purpose of Order L–208 and its amendment was to provide additional manpower and equipment for mines producing metals more vitally needed than gold—particularly copper mines. To induce such a shift of labor the War Manpower Commission ruled that no former gold miner could obtain a new job west of the Mississippi without the approval of the United States Employment Service, and this Service was instructed to assign former gold miners only to nonferrous mining jobs, except in cases of undue hardship.

In 1941 Order L–208 would have affected over 250 lode mines and possibly 700 placers in the United States and Alaska, operations that employed over 20,000 men. However, by October 1942 so many of

Digitized by Google

these men had joined the armed forces or had gone into the numerous war industries that the number employed was very greatly reduced. Of those remaining, many for various reasons were unsuited to be transferred to other mining camps or were needed to maintain equipment and properties during the closing period.

Order L–208 provoked much discussion, both for and against the order. One group contended vigorously that many gold-mining communities were isolated and their economic life was more vulnerable than that of industrial centers; that so few men could be made available for other work by the closing order that the cost would outweigh the gain; that the Government continued to supply gold miners in other countries and to buy their output while the gold mines in the United States were singled out from a host of industries regarded as nonessential and made the victims of direct action; and that gold miners and their families could contribute much greater net gain to the war program under a much less drastic order.

The other group asserted with equal intensity that the order testified eloquently to the uselessness of gold as a means of financing our war program; that our continued acceptance of gold from South Africa, Canada, and Russia was due primarily to a desire not to disrupt the domestic economy of our Allies or to put additional obstacles in the way of their paying for needed American goods; that no such political expediency made it necessary to continue producing gold from domestic mines; that it was folly to waste manpower by extracting more gold from the earth and interring it in Government vaults; that localized disturbances to the domestic economy brought about by closing the gold mines would be severe but that they would be insignificant compared with the Nation-wide industrial dislocations resulting from conversions to a wartime basis; and that the closing of gold mines should be followed by increased production of critical metals so urgently needed for war materials.

Silver.—Gold did not stand alone with respect to regulation and heated discussion—silver came in for an even greater share, and scarcely a month went by that some action was not taken or attempted. Feeling ran high at times and was vigorously expressed on the floors of Congress, in committee rooms, through the press, and over the radio.

Early in the year agitation became strong for silver to do its full share in the war, and to further this objective Secretary Morgenthau announced in February that he had recommended that all silver legislation be struck off the books to get silver into greater productive service.

The Treasury Department held at this time about 47,000 tons (1,360,000,000 ounces) of "free" or unallocated silver—that is, silver not needed as coin or as a reserve against outstanding silver certificates, which, when lent, must be returned; it cannot be consumed. On April 7 the Attorney General ruled that the Treasury Department could legally issue this silver to war-production plants for nonconsumptive purposes, and on May 6 an agreement was made for leasing unpledged bullion to the Defense Plant Corporation and for delivering it as needed for manufacture into nonconsumable forms.

Silver was included under the General Maximum Price Regulation issued on April 28 by the Office of Price Administration, and the provision became effective May 11 for bullion and May 18 for articles

Digitized by Google

sold at retail. But the ceiling price of 35⅝ cents per ounce on bullion from foreign countries did not apply in Mexico, and soon considerable bullion was being purchased there at a substantial premium and imported into the United States.

Increased demands by both essential and nonessential users and decline in supplies from normal sources soon created a shortage of the metal, so that early in July the Bureau of Industrial Conservation recommended that silver no longer be used as a substitute for other scarce metals. The situation rapidly became worse, and on July 21 silver was placed on the restricted list of imports by the War Production Board. Under this provision the private importation, sale, processing, or shipment of silver beyond the place of initial storage was prohibited, except by special authorization from the Board.

On July 29, the Board ruled (Conservation Order M–199) that after October 1 no foreign silver could be purchased or processed for certain nonessential civilian uses, except to fill orders with a preference rating of A–3 or higher. Also, from July 29 to October 1 no manufacturer might purchase or put into process for such restricted uses foreign silver in excess of 1 month's supply, based on his average consumption for 1941 or the first half of 1942.

Effective August 10, the Office of Price Administration established a ceiling price of 35⅝ cents an ounce on all imports of silver bullion. This attempt at price control proved unsatisfactory, so that another order was issued, effective August 31, whereby importers were authorized to pay up to 45 cents an ounce for Mexican silver. Corresponding price increases, authorized in September, for all silver bullion, for semifabricated products containing silver, and for scrap silver established generally a price of 45 cents an ounce for foreign silver.

Likewise, late in August the Office of Price Administration issued an order providing that semifabricating companies, makers of silver sheets, blanks, and similar articles, could pay the Treasury price of 71.11 cents an ounce for silver and pass the increased cost to the fabricating consumer; the previous price level had been fixed on a basis of silver costing 35⅝ cents an ounce.

On September 17 Secretary Morgenthau announced that the Treasury had 5,000,000 ounces of "silver ordinary," that is, silver not acquired under silver monetary legislation, which could be sold outright at 45 cents an ounce to industrial users with high priority ratings on recommendation of the War Production Board. Priority orders on hand failed to absorb all this silver.

Demands for the release of Treasury silver continued to grow during the year. The Silver Users Emergency Committee, formed early in September, was very active in influencing Congress and the public toward proposed legislation that would make available to both essential and nonessential industries the ample supply of Treasury silver not actually in the form of coinage. At no time, however, did the committee advocate repeal of the Silver Purchase Act.

The sentiments of certain groups were crystallized in a number of bills introduced in Congress late in 1942 and early in 1943. On September 14 Senator Green introduced a bill (S. 2768) designed to remove the restrictions on the use of silver after purchase in order that it might be used for consumptive as well as nonconsumptive purposes, provided that no silver was to be sold at less than its cost to the

Digitized by Google

United States or at less than the then current market price, whichever was higher; also, that the Government should maintain sufficient silver to cover all outstanding silver certificates. The Green bill was amended to include minor changes, but the Senate adjourned without passing the bill in any form. The Celler bill, introduced on September 17, proposed the repeal of all provisions of the Silver Purchase Acts of 1934 and 1939, but, like the Green bill, it failed to pass.

Several bills on silver legislation were offered in January 1943, among them the Green bill (S. 35), in much the same form as in 1942; the Celler bill (H. R. 823), essentially a Green bill for the House of Representatives; the Treadway bill (H. R. 102), calling for outright repeal of the Silver Purchase Acts; and the Murdock bill (S. 192), under which fabricators might purchase silver to be used exclusively for consumption purposes from stocks owned by the Government.

Frequent and heated arguments on the silver question came from the press and over the radio. One group took the stand that to continue to buy silver at prices above the world market for monetary purposes was so glaringly stupid that steps should be taken immediately to repeal the Silver Purchase Acts; that the orders on silver issued by the Office of Price Administration continued to maintain the subsidy to our silver mines by making semifabricators pay the subsidy themselves and pass the charge to the customers; that the orders increased the cost of silver to our armament industries; that they were a concession to the Mexican Government, which profited thereby because we failed to make proper use of the ample supply held by our own Treasury; that the Green bill was endorsed by the Treasury, the armed services, the War Production Board, and many others; that as a substitute for tin, copper, cadmium, nickel, aluminum, antimony, tungsten, and other metals, the Government silver hoard was a valuable stock pile but kept by the Treasury this hoard was useless; that used in airplane and other engines this silver would help sweep the Japanese from the seas; in vital parts for tanks and trucks, it would help annihilate Hitler; but buried at West Point, it was a monument to folly.

The other group stoutly held that the enemies of silver were seeking to use the intrinsic value of the metal for war purposes as a vehicle to strike down silver as money; that history teaches that silver is the oldest and best monetary metal and that it is the only legal money of the United States today; that as an economic weapon at the peace table, our great supply of silver will be equally as potent as in war; that an abundance of silver had been coming on the market to meet the demands of American war industries; that complaints of insufficient silver came not from war industries but from manufacturers of nonessential articles who were out to make a larger profit in advocating the enactment of a law that would give them the privilege of buying United States Treasury silver that was acquired solely for use as money; and that so much silver is now a byproduct of base-metal mining that to lower the price of silver would deal a serious blow to the economic stability of the base-metal mining industry.

DOMESTIC REFINERY PRODUCTION

The figures in the following table were obtained through cooperation between the United States Bureau of the Mint and the Bureau of Mines and were agreed upon after conference and adjustment between the two Bureaus.

The State totals are based upon bullion deposits in the United States mints and assay offices and upon returns to the Bureau of the Mint from smelting and refining companies. The State distribution is adjusted further by the Bureau of Mines from its geographical records of sources and production, both historical and current, from the producing mines and is tabulated for the mine reports discussed later. The data for the total production and in part for the distribution are obtained from records of (1) the unrefined domestic gold and silver deposited in the United States mints and assay offices; (2) the domestic gold and silver in fine bars reported by private refineries, supplemented by data of content of unrefined mattes, blister copper, copper anodes, and lead bullion; and (3) the unrefined domestic gold and silver contained in ore and matte exported for reduction. The last item is small.

Gold and silver produced in the United States, 1938–42, and approximate distribution of source, by States and Territories, in 1942

[Refinery figures supplied by U. S. Bureau of the Mint]

State or Territory	Gold [1]		Silver [2]

Gold and silver produced in the United States, 1792–1942

[From Report of the Director of the Mint. The estimate for 1792–1873 is by R. W. Raymond, commissioner of mining statistics, and since then by the Director of the Mint]

Period	Gold		Silver	
	Fine ounces	Value [1]	Fine ounces	Value [2]
1792–1847	1,187,170	$24,537,000	309,500	$404,500
1848–72	58,279,778	1,204,750,000	118,568,200	157,749,900
1873–1942	211,700,035	4,982,088,500	3,666,522,549	2,755,210,678
	271,166,983	6,211,375,500	3,785,400,249	2,913,365,078

[1] Gold valued in 1934 and thereafter at $35 per fine ounce; prior thereto at $20.67+per fine ounce. Dollar figures are rounded.

[2] Silver valued in 1934 and thereafter at Government's average buying price for domestic product: In 1934 and 1938 at $0.64+per fine ounce, in 1935 at $0.71875, in 1936 at $0.7745, in 1937 at $0.7735, in 1939 at $0.678787+, and in 1940–42 at $0.7111+.

The average commercial value per fine ounce of silver for the total recorded domestic production is $0.770.

PRICES OF GOLD AND SILVER

Gold.—Under the Gold Reserve Act of 1934 the value of gold was fixed by Presidential proclamation on January 31, 1934, at $35 per fine troy ounce and has remained at that figure through 1942. From

January 18, 1837,[1] through 1932, the price was $20.67+ per ounce, and in 1933 the legal coinage value was continued at $20.67+. The average weighted price per fine ounce in 1933, as computed by the Bureau of Mines, was $25.56 and in 1934, $34.95. A complete account of regulations pertaining to gold and silver in 1933–34 is given in the chapter on Gold and Silver in Minerals Yearbook, 1934 (pp. 25–46), issued by the Bureau of Mines.

Silver.—The Government price for newly mined domestic silver was maintained throughout 1938 and to June 30, 1939, at $0.646464646+ per fine ounce. The act of Congress approved July 6, 1939, fixed the price of domestic silver mined after July 1, 1939, at $0.711+ per ounce. The annual average prices[2] used for domestic silver from 1932 to 1939 are as follows: 1932, $0.282; 1933, $0.350; 1934, $0.646464646+; 1935, $0.71875; 1936, $0.7745; 1937, $0.7735; 1938, $0.646464646+; 1939, $0.678787878+; 1940–42, $0.711111111+.

UNITED STATES AND WORLD MONETARY STOCKS

According to figures published in the Federal Reserve Bulletin, the gold reserves of the United States totaled $22,726,000,000 at the end of 1942, a decline of $11,000,000 during the year. This reversal of trend was caused by net sales to foreign countries exceeding the flow of domestic gold.

Figures are not available for the gold reserves held at the end of 1942 by central banks and governments in many other countries of the world. However, by using the data available for 1942 and making certain assumptions based on the latest figures available for past years, it is believed that the total reserves of the world amount to approximately $33,000,000,000, including stabilization funds. On this basis, the reserves of the United States constitute about 70 percent of the world total.

United States Treasury silver holdings at the close of 1942 approximated 3,334,000,000 ounces, a gain of about 54,000,000 ounces over 1941. The holdings for 1942 represent nearly 115,000 tons of the metal.

The Twenty-seventh Annual Review of the Silver Market, 1942, by Handy & Harman, contains the following paragraphs regarding silver purchases and coinage:

> At the end of the year gold holdings of the United States were practically unchanged from the 1941 closing figures. Therefore, the year's addition of even a scant 60,000,000 ounces to the silver holdings permitted some slight progress toward the goal set by the Silver Purchase Act that "one-fourth of the total monetary value of the gold and silver stocks shall be in silver." The proportion of silver at December 31, 1942, was 16 percent, an advance of 1/10 percent since December 31, 1941.
>
> *Coinage.*—Information from London indicates that the Royal Mint coined British Treasury silver acquired from the Indian Government, but the amount is unknown. Maria Theresa thalers, for export to Abyssinia, were minted, as well as some Colonial and domestic coinage. We are also advised that the Royal Mint of Canada purchased silver from that country's producers for current coinage purposes, and that the Bank of Mexico bought metal, part of which was to be minted for a South American country.
>
> According to an official statement, the amount of silver received at the United States mints during the first eleven months of 1942 for the purpose of foreign

Digitized by Google

coinage manufacture was 8,991,000 fine ounces, some of which was bought outside of the United States. The identity of the countries obtaining this coinage was withheld.

A new high record for domestic silver coinage was made in 1942, the 11-month figure of 69,100,000 ounces being 16,900,000 ounces greater than the previous full year's record established in 1941. Of the total, 66,376,000 ounces were consumed in subsidiary coinage which excludes nickels and pennies, and 2,744,000 ounces were used in the new "silver" nickels. These latter coins contain 35 percent silver, 56 percent copper, and 9 percent manganese.

Under legislation enacted toward the end of December, Secretary Morgenthau established specifications for a new, wartime 1-cent coin, of the same design as the present penny, but made of zinc-coated steel. Minting of the new pennies will commence about February 1, 1943, and subsequently a 3-cent piece, also authorized under the recent law, may be put into circulation if the demand for minor coins continues.

CONSUMPTION AND USES

Gold.—The desirable properties and uses of gold in industry were described in considerable detail in the Gold and Silver chapter, Minerals Yearbook, 1941. In 1942 the war program called for substantially greater quantities of gold wire in instruments used in measuring the speeds of aircraft engines, gold-plated anodes for sound-transmitting apparatus, gold-alloy hair springs for use in highly accurate timepieces and marine chronometers, gold lining for special pieces of base-metal equipment used in chemical plants, gold-lined equipment for the artificial silk industry, and gold chloride for use in making colored film. Greater use of gold in the war program is necessarily restricted by the high price of the metal, and under present conditions it cannot hope to substitute in any great amount for critical base metals.

Normally, 5 to 10 percent of the world output of gold is consumed by industry; the remaining 90 to 95 percent is used for monetary purposes. Industry in the United States in 1941 consumed approximately 2,000,000 ounces of gold, both old and new metal. This amount was divided about as follows: Jewelry, 950,000 ounces; watch cases, 75,000 ounces; gold leaf, 60,000 ounces; electrical and industrial equipment, instruments, and medical and dental supplies, 915,000 ounces.[3]

Silver.—Consumption of industrial silver continued to mount rapidly in 1942, rising to an estimated gross amount of about 120,500,000 ounces.[3] Distribution by uses is estimated to have been as follows:

Silverware	34,000,000	Brazing alloys	[1]
Photographic goods	19,600,000	Solder	[1]
Jewelry	16,500,000	Chemical products, n. e. s.	[1]
Bearings	10,600,000	Miscellaneous	21,300,000
Contacts	9,300,000		
Insignia	7,000,000	Total	120,500,000
Dental and medical	2,200,000		

[1] Included elsewhere.

Greatest gains were in the use of silver for bearings, solders, brazing alloys, electrical contacts, photographic goods, insignia, and dental and medical supplies. These uses are expected to require much greater quantities of the metal in 1943 (except for insignia), but consumption of silver in jewlery and silverware will drop greatly.

[3] War Production Board, data as of May 14, 1943.

Digitized by Google

Nearly 60 percent of the silver consumed in the United States in 1942 probably went into war production; this proportion will be even greater in 1943. The large quantities used for solders and brazing alloys, electrical appliances, bearings, and other articles played a vital part in the production of virtually every airplane, tank, submarine, battleship, cargo ship, and field kitchen and in many kinds of instruments, guns, bombs, torpedoes, shells, and other weapons. Much silver was also used in highly important military photography, and smaller amounts for medical and dental work.

Much progress was made in utilizing the minimum 1,000,000,000 ounces (34,286 short tons) of "free" or nonconsumable silver loaned by the Treasury to the Defense Plant Corporation, under agreement of May 6, 1942, and allocated by the War Production Board. Late in 1942 the Board announced that all such silver either had been loaned to war industries or commitments had been made for its use, and by January 1943 some 22,000 tons had been shipped from the vaults. By far the greatest part of the metal went into bus bars for use in aluminum and magnesium plants, saving a substantial tonnage of copper.

The following table shows the net industrial consumption of gold and silver in the United States for the 10-year period 1933–42, inclusive, in terms of dollars for gold and fine ounces for silver. The quantity of each metal reclaimed and recovered from various sources is deducted from that issued for industrial use to give the net amount.

Net industrial consumption of gold and silver in the United States, 1933–42[1]

Year	Gold (dollars)			Silver (fine ounces)		
	Returned from industrial use	Issued for industrial use	Net industrial consumption	Returned from industrial use	Issued for industrial use	Net industrial consumption

DOMESTIC SUPPLY

The following tables show the sources of domestic supply of gold and silver, by percent, for 1936–42. It is noted that during this period dry and siliceous ores and placer gravels supplied 86 to 90 percent of total United States gold production, exclusive of the Philippine Islands and Puerto Rico; base-metal ores supplied the remaining 10 to 14 percent. On the whole, placers have increased in relative importance in gold production since 1928, and dry and siliceous ores have steadily decreased in relative importance since 1932.

In the production of silver dry and siliceous ores are less important than in the production of gold, and placers are almost of no consequence. In only 1 year during the past 20 years (1938) have dry and siliceous ores supplied as much as half of the total United States output of silver. The low point was reached in 1928, when these ores supplied only 19 percent, and base-metal ores 81 percent.

Mine production of gold in the United States, 1936–42, by percent from sources, and in total fine ounces [1] [2]

Year	Percent from—						Total fine ounces
	Placers	Dry and siliceous ore	Copper ore	Lead ore	Zinc ore	Zinc-lead, zinc-copper, lead-copper, and zinc-lead-copper ores	
1936	23.9	64.0	10.0	0.5	(3)	1.6	3,782,669

MINE REPORT

METHOD OF COLLECTING STATISTICS

The second table in this report presents the official refinery figures for production of gold and silver in the United States from 1938 to 1942, as agreed upon by the Bureau of the Mint and the Bureau of Mines. These figures record the output of gold and silver bullion from domestic ore in marketable form as metals, either refined or unrefined.

To trace the gold and silver produced back to its source by States, counties, and mining districts, the Bureau of Mines systematically investigates the "mine production" of ores containing gold and silver and the output of the placer mines, the total being classified by methods of production and by kinds of ore, as well as by mining districts. The resulting figures form the basis of the mine reports.

Of the two systems for ascertaining the production of gold and silver, one is a measure of the metallurgic industry and the other of the mining industry; one reports the metal actually recovered in marketable form and the other the mine output and its recoverable content. The two methods will not produce identical results, but data for a period of years long enough to compensate for overlap or lag should agree within allowable limits of error.

Compared with the mine reports, the mint reports for the 38 years show a total excess of gold of 297,374 ounces (a difference of 0.21 percent) and a total excess of silver of 12,848,477 ounces (a difference of 0.58 percent).

Gold and silver produced in the United States, 1905–42, in fine ounces, according to mint and mine returns, in terms of recovered metals

Year	Mint		Mine	
	Gold	Silver	Gold	Silver
1905–37	114, 224, 734	1, 898, 028, 783	114, 024, 647	1, 887, 909, 257
1938	5, 089, 811	62, 665, 335	5, 170, 743	62, 873, 450
1939	5, 611, 171	65, 119, 513	5, 672, 485	65, 565, 024
1940	6, 003, 105	69, 585, 734	5, 984, 163	71, 824, 746
1941	5, 976, 419	72, 336, 029	5, 881, 798	68, 483, 333
1942	3, 741, 806	56, 090, 855	3, 615, 836	54, 321, 962
	140, 647, 046	2, 223, 826, 249	140, 349, 672	2, 210, 977, 772

UNITS OF MEASUREMENTS

All tonnage figures are short tons of 2,000 pounds "dry weight"; that is, they do not include moisture. The weight unit for gold and silver is the troy ounce (480 grains). The totals are calculated upon the basis of recovered and recoverable fine gold and silver shown by assays to be contained in ore, bullion, and other material produced. Prices of gold and silver are discussed in a preceding section of this report.

MINES PRODUCING

LEADING GOLD PRODUCERS

The output of the 29 largest gold producers in the United States (Philippine Islands and Puerto Rico excluded) in 1942, none of which produced less than 17,000 ounces, was 2,086,084 fine ounces (60 percent

Digitized by Google

of the total). Six of the companies working placer mines (five with floating connected-bucket dredges and one with a dragline dredge) recovered 421,818 ounces of gold; the rest of the output of the largest producers came from lode mines. The total output of lode mines and placers producing less than 17,000 ounces each was 1,371,026 ounces.

Largest producers of gold in the United States in 1942, in order of output [1]

Rank	Operator	State	Mining district	Source of gold
1	Homestake Mining Co.	South Dakota	Whitewood	Dry and siliceous gold ore.
2	Utah Copper Co.	Utah	West Mountain	Copper ore.
3	United States Smelting, Refining & Mining Co.	Alaska	Fairbanks and Nome	Dredging gravel.
4	Phelps Dodge Corporation	Arizona	Ajo, Copper Mountain, Verde, Warren.	Copper ore, dry and siliceous gold ore, dry and siliceous silver ore.
5	Golden Cycle Corporation [2]	Colorado	Cripple Creek, etc.	Dry and siliceous gold ore.
6	Yuba Consolidated Gold Fields.	California	Callahan, Oroville, Yuba River.	Dredging gravel.
7	Alaska Juneau Gold Mining Co.	Alaska	Juneau	Dry and siliceous gold ore.
8	Natomas Co.	California	Folsom	Dredging gravel.
9	Empire Star Mines Co., Ltd.	do	Browns Valley, Grass Valley-Nevada City.	Dry and siliceous ore.
10	Idaho Maryland Mines Corporation.	do	Grass Valley-Nevada City.	Do.

14	Lava Cap Gold Mining Corporation.	California	Grass Valley-Nevada City.	Dry and siliceous ore.
15	Consolidated Coppermines Corporation.	Nevada	Robinson	Copper ore.
16	United States Smelting, Refining & Mining Co.	Utah	West Mountain	Zinc-lead ore, lead ore, dry and siliceous gold-silver ore.
17	Alaska-Pacific Consolidated Mining Co.	Alaska	Willow Creek	Dry and siliceous gold ore.
18	Mammoth-St. Anthony, Ltd.	Arizona	Old Hat	Zinc-lead ore, dry and siliceous gold ore.
19	Manhattan Gold Dredging Co.	Nevada	Manhattan	Dredging gravel.
20	Talache Mines, Inc.	Idaho	Middle Boise	Dry and siliceous gold ore.
21	Capital Dredging Co.	California	Folsom	Dredging gravel.
22	Bald Mountain Mining Co.	South Dakota	Trojan	Dry and siliceous gold ore.
23	Dayton Dredging Co.	Nevada	Silver City	Dredging gravel.
24	United States Smelting, Refining & Mining Co. (Gold Road).	Arizona	San Francisco	Dry and siliceous gold ore.
25	Golden Queen Mining Co.	California	Mojave	Dry and siliceous ore.
26	Telluride Mines, Inc.	Colorado	Upper San Miguel	Dry and siliceous gold-silver ore.
27	Knob Hill Mines, Inc.	Washington	Republic	Dry and siliceous gold ore.
28	Anaconda Copper Mining Co.	Montana	Summit Valley or Butte.	Copper ore, zinc-lead ore, dry and siliceous silver ore.
29	Cactus Mines Co.	California	Mojave	Dry and siliceous ore.

[1] Philippine Islands excluded.
[2] Custom mill. Includes mainly ore from Cresson, Portland, Ajax, Vindicator, and other mines in Cripple Creek district, Colorado, but also from other districts in Colorado.

LEADING SILVER PRODUCERS

The output of silver from the 48 leading silver-producing companies in 1942, none of which produced less than 180,000 ounces, was 43,426,353 ounces—80 percent of the total mine output of the United States (Philippine Islands and Puerto Rico excluded); the remaining 10,523,543 ounces (placer production excluded) came from about 2,600 lode mines, many of which derive a substantial net income from the silver content.

Largest producers of silver in the United States in 1942, in order of output—Continued

Rank	Operator	State	Mining district	Source of silver
39	Shoshone Mines, Inc	California	Resting Springs	Lead ore.
40	Combined Metals Reduction Co. (Butterfield mine).	Utah	West Mountain	Zinc-lead ore, dry and siliceous gold ore.
41	DeLamar Milling Corporation.	Idaho	Carson or French Creek.	Dry and siliceous gold-silver ore.
42	Telluride Mines, Inc	Colorado	Upper San Miguel	Do.
43	Combined Metals Reduction Co.	Nevada	Pioche	Zinc-lead ore.
44	Mike Horse Mining & Milling Co.	Montana	Heddleston	Do.
45	Blackhawk Consolidated Mines Co.	New Mexico	Mogollon	Dry and siliceous gold-silver ore.
46	Golden Queen Mining Co	California	Mojave	Dry and siliceous ore.
47	Tamarack & Custer Consolidated Mining Co.	Idaho	Placer Center	Zinc-lead ore.
48	Dayrock Mining Co	do	do	Lead ore.

NUMBER OF MINES

The following table indicates the number of mines that produced gold and silver in 1941 and 1942. The placers are those in which gold and silver in natural alloy and, in a few placers, platinum are recovered from gravel and sand, whether by hand washing, sluicing, hydraulicking, drifting (in frozen ground or ancient buried river channels), or dredging. The lode mines are those yielding gold and silver from ore as distinguished from gravel, mainly from underground workings, and include those that yield ore mined chiefly for copper, lead, or zinc but that contribute the precious metals as byproducts. In addition to the producing mines enumerated here many properties were being prospected and developed, and many other mining claims were being held by assessment work only.

The enumeration of placer mines is less satisfactory than that of lode mines, because some are operated only temporarily and are individually small. As far as possible the unit, as for lode mines, is not the operator but the mining claim or group of claims.

Number of mines in the United States producing gold and silver, 1941–42, by States

State	Lode		Placer		Total

MINE PRODUCTION

SUMMARY

The following table gives the mine production of gold and silver in 1941 and 1942, by States, in terms of recovered metals, as calculated by the Bureau of Mines from reports from the producing mines. The annual percentage gains in gold production in the years following the 69-percent increase in the price of gold are as follows: 1934 over 1933, 19 percent; 1935 over 1934, 18 percent; 1936 over 1935, 19 percent; 1937 over 1936, 9 percent; 1938 over 1937, 7 percent; 1939 over 1938, 10 percent; 1940 over 1939, 5 percent; but 1941 decreased from 1940, 2 percent; and 1942 decreased from 1941, 27 percent. The total gain in 1940 over 1933 was 128 percent. The output of silver decreased 20 percent in 1942 from 1941 but was 133 percent above that in 1933.

ORE PRODUCTION, CLASSIFICATION, METAL YIELD, AND METHODS OF RECOVERY

The best index of lode mining is the quantity and metallic content of ore mined rather than the number of mines or operators. The following tables give details of classes of ore, metal yield in fine ounces of gold and silver to the ton, and gold and silver output by classes of ore and by methods of recovery, embracing all ores that produced gold and silver in the United States (excluding the Philippine Islands and Puerto Rico) in 1942. The individual State chapters from which these tables were compiled contain additional tables and text on the subject and may be found elsewhere in this volume.

The classification originally adopted in 1905 on the basis of smelter terminology, smelter settlement contracts, and smelter recovery has been used continuously in succeeding years, except for modifications necessitated by the improvement in recovery of metals and the lowering of grade of complex ores treated, accomplished by improved mill concentration processes. A "dry" ore is one that carries so little lead or copper that by itself in quantity it would not satisfy the requirements for the smelter charge in lead smelting or copper smelting, respectively. The copper ores include those smelting ores that contain 2.5 percent dry assay or more of copper (or less than this percentage if no other metal is present), or those ores concentrated chiefly for their copper content. The lead ores are those that contain 5 percent dry assay (minimum lead smelting charge requires 7.5 to 8.5 percent wet assay) or more of lead, irrespective of precious-metal content; an ore that carries any grade of lead exclusively is called a lead ore. Zinc smelting ores (chiefly oxides) range from 16 to 45 percent zinc; zinc concentrating ores include any grade of zinc ore that makes marketable zinc concentrate, irrespective of precious-metal content. The mixed ores are combinations of those enumerated. The smelter classification applies to concentrates.

Siliceous (silica[5] in excess of iron) gold, gold-silver, and silver ores containing too little copper, lead, or zinc to be classified as copper, lead, zinc, or mixed ores are called "dry" ores regardless of the ratio of concentration, except low-grade ore milled chiefly for its copper content and having very little or no precious-metal content (chiefly the "porphyry coppers") and ores from which separate products of lead concentrates and zinc concentrates are made. The crude ore into the mill in these two exceptional instances thus takes its name from its products—a name that is also justified by the mineralogical content and final recovery of metals. The "dry and siliceous ores" thus, by elimination, include both dry siliceous and irony, but chiefly siliceous, ores valuable for their gold and silver content, regardless of method of treatment, and dry fluxing ores carrying considerable quantities of iron and manganese oxides, or iron sulfide, and very small quantities of gold and silver. Dry and siliceous gold ores are those that by inspection are overwhelmingly of gold content; a similar qualification applies to silver ores; decision as to "gold-silver" ore is made arbitrarily on a basis of value, using the rule that the metal of lower value is not used in the bimetal classification unless its value is equal to or over one-quarter of the combined value of gold and silver.

The lead, zinc, and zinc-lead ores in most districts in the Eastern

[5] Except where mineralization approaches a matte, ores in their natural state generally contain more silica than iron and usually are highly siliceous.

Digitized by Google

and Central States carry no appreciable quantity of gold or silver; such ores are excluded from this report unless otherwise indicated.

PLACERS

DREDGING

Placer gold is obtained largely from gravels handled by connected-bucket floating dredges, which recovered approximately 68 percent of the total output from placers in the United States (Philippine Islands and Puerto Rico excluded) in 1942 and 58 percent in 1941. The quantity of gold recovered by dredges from the inception of the industry as a commercial factor in 1896 to the end of 1942 is recorded as 19,074,071 ounces, originating by States as follows: California, 11,566,916 ounces; Alaska, 5,158,064 (including the production from two Becker-Hopkins single-dipper dredges and some gold by hydraulicking); Montana, 691,083; Idaho, 612,291; Colorado, 455,195;

Digitized by Google

Oregon, 467,046; and other States, 123,476. The output in 1942 was 689,069 ounces from 102 dredges, of which California produced 310,937 ounces from 44 dredges; Alaska, 249,868 ounces from 31 dredges; Idaho, 36,631 ounces from 10 dredges; Montana, 31,283 ounces from 7 dredges; Oregon, 21,641 ounces from 6 dredges; and Colorado, 14,523 ounces from 3 dredges.

OTHER PLACER-MINING METHODS

From 1932 through 1942 dragline and power-shovel excavators operated in connection with dry-land floating amalgamating and sluicing plants have been widely used in placer mining. In 1942 approximately 28 percent of the total output of placer gold, excluding that of Alaska and the Philippine Islands, was recovered at such plants, and 5 percent was produced by old-established mining methods, such as hydraulicking, drift mining, sluicing, and rocking.

Digitized by Google

Additional information on placer-mining methods may be found in the State reviews in the Minerals Yearbook and Mineral Resources series.

EMPLOYMENT AND PRODUCTION

Statistics on employment and production in the gold and silver industry are presented for the first time in Minerals Yearbook. Data are given for 1941 only; figures for 1942 are incomplete. Mine and mill employees are classified according to the methods described in this volume in the chapter on Employment and Accidents in the Mineral Industries. Gold, gold-silver, and silver ores are classified on the basis of the methods described in the earlier pages of the chapter on Gold and Silver.

WORLD ASPECTS

WORLD PRODUCTION

According to the Bureau of the Mint, the world output of gold and silver from 1493 to 1941 is 1,415,496,883 fine ounces of gold valued at $33,321,716,914 and 17,507,210,287 fine ounces of silver valued at $15,543,504,556 (see figs. 2 and 3).

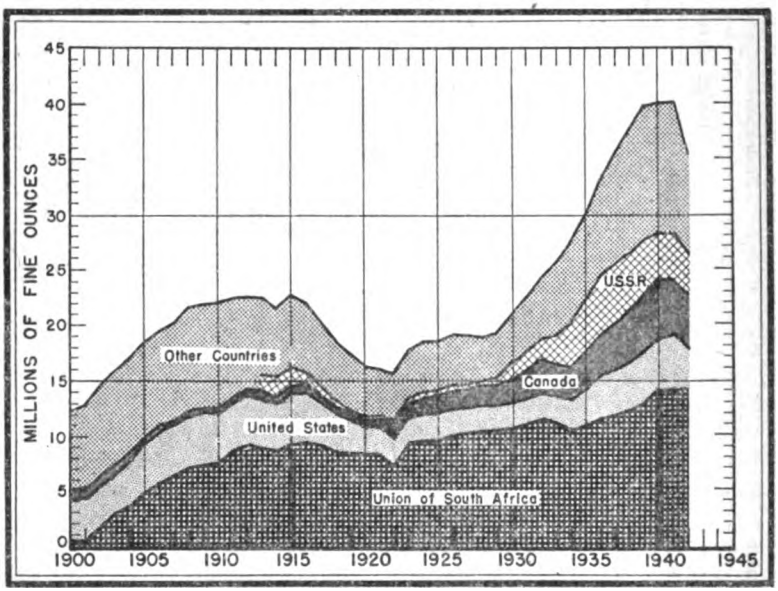

FIGURE 2.—World production of gold, 1900–42. (Figures for 1942 are preliminary.)

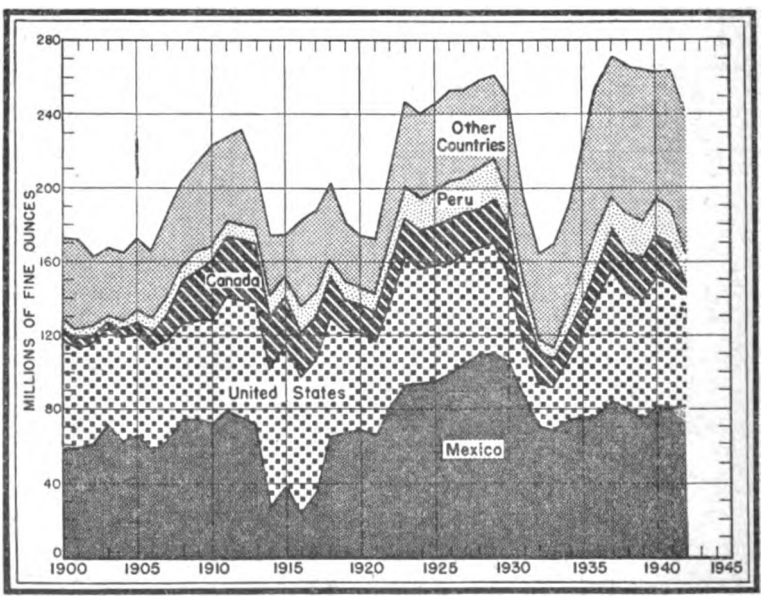

FIGURE 3.—World production of silver, 1900–42. (Figures for 1942 are preliminary.)

[1] Preliminary world gold production table prepared with revisions and adjustments by B. B. Waldbauer, Foreign Minerals Division, and Frederick Betz, Metal Economics Division, Bureau of Mines, in cooperation with the Office of the Director of the Mint. Figures used were derived in part from the Statistical Yearbook of the League of Nations and from the American Bureau of Metal Statistics. No official statistics are issued by Government of U. S. S. R., consequently figures released by the various authorities vary widely and are irreconcilable. In some countries accurate figures are not possible to obtain owing to clandestine trade in gold.

[2] Refinery production.

[3] Approximate production.

[4] Data not available. Estimate included in total.

[5] Exports.

[6] Imports into United States.

[7] Purchases by the State Central Bank.

[8] Conjectural figure published by the American Bureau of Metal Statistics (New York), Annual Issue.

[9] Beginning with 1939, Burmese production included with British India.

[10] Beginning with 1941, production of Ruanda and Urundi included with Belgian Congo.

Preliminary world silver production table prepared with revisions and adjustments by B. B. Waldbauer, Foreign Minerals Division, and Frederick Betz, Metal Economics Division, Bureau of Mines, in cooperation with the Office of the Director of the Mint. No official statistics are issued by Government of U. S. S. R., consequently figures released by the various authorities vary widely and are irreconcilable.

REVIEW BY COUNTRIES

Data on gold and silver mining in countries outside the United States were even less complete in 1942 than in 1941. Naturally, the Philippine Islands, with their production of over 1,000,000 ounces of gold in 1941, were removed completely from the picture, and many other countries have such rigid censorship regulations that little or no information has been released since 1939.

CANADA

Labor shortage was a primary problem in Canadian gold mines in 1942, but shortage of equipment was severely felt also. Operators were forced to eliminate all but essential development and to hire old men, women, and boys in an effort to keep the Mines open. Thousands left the gold camps to join the armed forces or to work in industrial centers farther south. It is reported that Porcupine lost 10,000 of its 41,000 people and Kirkland Lake 16,000 of its 23,000. By the end of the year half of the gold mines in British Columbia and 16 or 17 in Ontario and Quebec were closed. Output of ore at the great Hollinger mine in Ontario dropped from 5,200 tons daily to 3,500 tons. In the fall, about 600 men from Ontario gold mines were transferred to the Sudbury nickel mines, but the movement appears to have been only partly successful. It is stated that 25 percent of the men quit in a short time because of inadequate housing facilities, lack of qualifications for the Sudbury camp, different mining conditions, and inability to meet physical standards. However, these difficulties were being overcome, and indications were that the transfer of gold miners to base-metal mines would be more successful in the future.

No order as drastic as L–208 was issued by the Canadian Government. In contrast with the United States, Canada appeared to have adopted the policy of gradual curtailment of gold mining, no doubt

Digitized by Google

in recognition of the great dependence of Canadian economy on the gold industry and the utter ruin that whole communities would face by a sudden shut-down. In July the Government issued an order prohibiting the opening of new gold mines and limiting monthly tonnage in mines then open to the average of the first 4 months of the year. A few months later the Premier stated that action must be taken to curtail gold production further, that plans would be carried out in step with war requirements, and that due regard would be given the industry so that it would function soundly in the postwar period. This policy, together with Allied successes on the war front, created a general feeling of optimism, so that gold stocks on the Toronto exchange remained strong throughout the year.

Gold output in Canada in 1942 declined over 500,000 ounces from 1941, but despite this decrease the value of gold was 47 percent of the value of all metals produced and 33 percent of the value of all minerals produced in the Dominion. Gold lodes supplied 85 percent of the total gold; placers and base-metal deposits, 15 percent. Gold and silver production in 1942 was distributed among the various provinces as follows:

Province:	*Gold, fine ounces*	*Silver, fine ounces*
Ontario	2,756,922	4,426,977
Quebec	1,101,533	1,649,292
British Columbia	470,254	10,617,278
Saskatchewan	173,361	2,603,748
Manitoba	138,666	845,849
Northwest Territories	97,039	22,433
Yukon	79,058	506,002
Nova Scotia	12,950	404
Alberta	32	3
Total	4,829,815	20,671,986

Ontario produced about 57 percent of Canadian output of gold in 1942. The gold-bearing quartz veins of the Porcupine and Kirkland Lake regions supplied 77 percent of the Province total and about 50 percent of the Dominion lode production. These two camps have increased their reserves in recent years, and the ore bodies show no signs of exhaustion. Gold ore milled in the Province in 1942 totaled 10,548,849 tons compared with 12,129,513 tons in 1941; 14 mills closed during the year.

MEXICO

The Republic of Mexico continued to hold first place as the world's leading silver producer in 1942 and contributed over 43 percent of the silver produced in the Western Hemisphere, compared with about 38 percent in 1941.

Hidalgo again was the leading State in Mexico in silver production, its output amounting to about 10 percent of the world output. Credit for this is due mainly to Real del Monte y Pachuca, the world's largest silver mine.

Chihuahua, Zacatecas, and San Luis Potosí also were large producers of silver, most of which was a byproduct from the smelting of zinc-lead ores. Six large base-metal mines in Chihuahua were important producers: The American Smelting and Refining Co. (three mines), El Potosí Mining Co., the San Francisco Mines of Mexico, Ltd., and the Moctezuma Lead Co. In Zacatecas two large base-metal mines—the Fresnillo Co. and Peñoles S. A.—were credited with

Digitized by Google

most of the State's output of silver. The Fresnillo Co. produces about three times as much silver as any other base-metal mine in Mexico. In San Luis Potosí, silver from base metals is produced mainly at the mines of the American Smelting & Refining Co. at Charcas, the Kildun y Anexas at Matehuala, and the María de la Paz y Anexas at La Paz. The base-metal mine of the American Smelting & Refining Co. at Angangueo in Michoacán continued to be a large producer of silver.

During the last decade, base-metal ores in Mexico have assumed increasing importance as sources of silver, whereas the importance of silver ore has declined. In 1935, about 75 percent of the silver in the Republic was derived from silver ore, which now contributes only about 55 percent; base-metal ores have risen not quite to 45 percent.

As in the past, gold production was not outstanding in Mexico in 1942. The largest gold mine is Dos Estrellas en El Oro y Tlalpujahua, S. C. L. in Michoacán, although the silver mine Real del Monte y Pachuca surpasses it in gold output.

CENTRAL AMERICA[6]

Costa Rica.—Mining in Costa Rica is virtually limited to gold mining. All producing districts are on the western slope of the mountains facing the Gulf of Nicoya. All the operations are small, the mills having a daily capacity of 5 to 50 tons of ore. Four companies mined substantial quantities of ore in 1942—the Abangarez holdings, the Compañia mine, the Juchem and Sanford operations, and the Bonanza mine (Rudin Co.). Total production for the country in 1942 approximated a value of $500,000. This is not a large amount, but it is a very important item in the economy of this little country.

Honduras.—Some quantity of gold and silver is mined in Honduras. Only two producers are recorded: The New York & Honduras Rosario Mining Co. at San Juancito and the Cia. Minera Agua Fria, S. A., near Delhi.

The Rosario mine, operating for 62 years, has a 500-ton mill and in 1941 produced 3,500,000 ounces of silver and 23,000 ounces of gold. The Agua Fria mine was opened in 1935; it has a 100-ton mill and in 1941 produced 12,000 ounces of gold and 16,000 ounces of silver. Ore reserves are relatively small.

Nicaragua.—1942 was the sixth consecutive year in which Nicaragua has led all Central American countries in gold production. The eight important operating companies, listed in order of output, were as follows: La Luz de Los Angeles; the Neptune Gold Mining Co.; Compañia Minera La India; Impresa de Nicaragua; Compañia Minera del Javali (operating continuously for 80 years); San Juan Mines, Inc.; Compañia Minas Matagalpa; and Compañia de San Gregorio. Quartz ores are the most important sources of gold. Transportation is the major problem in prospecting for gold ores and developing them.

SOUTH AMERICA

Golding mining declined in a number of South American countries in 1942 because of difficulty in getting machinery and supplies from the United States, a shortage of ships for transporting ores and con-

[6] Much that follows on Central and South America is taken from a series of articles on Gold and Silver in Latin America: Eng. and Min. Jour., vol. 143, No. 8, August 1942, pp. 75-115.

Digitized by Google

centrates to United States smelters, wage competitions in certain other industries, fear of foreign capital to make investments at this time, and the uncertain attitude of the United States toward a gold policy. This decline tended to disrupt to some extent the internal economies of several of these countries by reducing the amount of foreign exchange available for imports.

Argentina.—Formerly most of the gold in Argentina came from placers along the Andes, but more recently lodes have been developed and now produce 65 to 70 percent of the total output. Production is still small. The most important mine is El Oro, in the Province of La Rioja.

Brazil.—Although some gold is mined in nearly every State in Brazil, the major part comes from Minas Gerais. The Morro Velho, the largest producer, continued to increase its ore reserves and is now reported to have 8,000,000 tons blocked out. Progress was made also in minimizing the high temperature in this mine, the deepest in the world, by installing an extensive cooling and ventilating plant. The Morro Velho mill has a daily capacity of 1,000 tons of ore, which in 1942 averaged 11 grams of gold per ton.

Chile.—Before 1932, Chile's annual output of gold totaled only 30,000 ounces, derived largely from copper ores and concentrates. Since that date, the industry has expanded rapidly until it has reached or exceeded 300,000 ounces during at least 3 years. Lode deposits have increased in importance, and placers have declined. Much encouragement has been given small operators; as a result, thousands of gold mines have been discovered and worked since 1932. Most of the gold veins are found in the Coast Range or along the longitudinal valley running the length of the country and are genetically related to the great granodiorite intrusions so common in Chile. Generally the mines are shallow and work only the zone of secondary enrichment; the ore falls in grade in the primary zone at depth. The Provinces of Atacama and Coquimbo yield the bulk of production. In 1942 gold mining in Chile employeed about 30,000 men.

Colombia.—Gold, next to coffee, is the most important source of revenue in Colombia. It is stated that in 1942, 80,000 men were engaged in gold mining and 500,000 people derived a living from the industry in one way or another. The importance of gold in the economy of the country thus becomes very evident. The Department of Antioquia produced 60 percent of the total gold; the Intendencia of Chocó ranked second.

Slightly more than half of the gold output in Colombia comes from placers; the rest from gold lodes. In placer operations the larger companies use dredging; the smaller ones hydraulicking. Most of the dredges are along the San Juan, Porce, Cauca, and Supia Rivers. About 52 percent of the output comes from a few large but well-equipped foreign companies; 14 percent from medium-size companies, mostly Colombian-operated; and 34 percent from small operators. Silver and platinum are important byproducts of gold mining.

Ecuador.—As in 1941, the Portovelo mine (opened in 1896) of the South American Development Co. and the Macuchi mine of the Cotopaxi Exploration Co. produced the bulk of Ecuador's output of gold and silver. No information is available on the six other companies that did exploratory work in 1941.

Digitized by Google

Peru.—Peru easily takes first place among South American countries in output of silver. In 1942, about 60 percent of the output was derived from lead and copper ores. The Cerro de Pasco Copper Corporation was the largest producer and handled the ores of many smaller operators as well as its own. In output of gold, about 61 percent was supplied by gold lodes, 30 percent by base-metal ores, and 9 percent by placers. The gold-mining industry employed 9,000 of the Nation's 27,000 mining laborers and supplied 24 percent of the revenue accruing to the mining industry.

Venezuela.—In 1942, about 95 percent of Venezuela gold output came from the mines of the New Goldfields and the French Mocupia in the Callao district. Small operations declined, largely because of the attraction of diamond mining on Surukun River in the Great Savannah. Difficult transportation is a serious handicap to prospecting for gold in Venezuela.

AFRICA

South Africa.—The objective of South Africa was to maintain gold production during 1942 at the 1941 level, but rising costs and the reluctance of the United States and Great Britain to allocate supplies and shipping space pushed output down slightly. South Africa continued to lead by a wide margin all countries in the world in gold production. Output was 14,120,617 ounces compared with 14,386,361 ounces in 1941, a decline of less than 2 percent. To produce this quantity of gold, 66,979,700 tons of ore were treated, compared with 67,255,450 tons in 1941. The tenor of the ore has been steadily declining from 0.224 ounce of gold per ton in 1938 to 0.210 ounce per ton in 1942.

OCEANIA

Australia.—The position of Australian gold mines was reported to be uncertain in 1942. Operators claimed that the attitude of the Government was unsatisfactory in that it was first stated that the gold industry was vital to the Commonwealth and must be continued; yet the industry had been denuded of its best men for other work or for the armed forces; and the Government had established no sound policy to serve as a basis for planning and building in the future. Production in Western Australia slumped nearly 24 percent from the 1941 output.

New Guinea.—Information on New Guinea for 1942 is meager, but it is known that some gold mines were forced to close early in the year when buildings and equipment were destroyed by the invading Japanese army.

Tasmania.—For a number of years Tasmania has produced more than a million ounces of silver annually. Base-metal ores are the principal source, zinc-lead ores supplying over 70 percent. Base-metal ores also contribute most of the gold—zinc-lead ores 53 percent and copper ores 40 percent.

GENERAL SUMMARY

Copper may not have been the most critical metal in the war economy in 1942; but several authorities so termed it, and without question it was one of the top three on the list. On the whole, trends in the copper industry in 1942 were merely continuations and accentuations of those in evidence during 1941. Domestic mine and smelter production rose again in 1942, were each 13 percent above 1941, and were the largest annual amounts ever reported. Receipts of refined copper from abroad also continued to rise, and they established a new high record. Exports of copper, though above those in 1941, were again notably low as compared with most years in the twentieth century. Prices remained unchanged at ceilings fixed in 1941, but bonus payments offset the high cost of operations at some mines. Despite Government consumption-restriction orders on copper and efforts of the Government and others to encourage substitution of more abundant materials, military and essential civilian needs again could not be met. Consumption once more reached staggering heights, never previously attained.

Efforts of various Government agencies were directed more sharply than ever before toward increasing copper production from mines and scrap materials, toward greater imports (particularly of the higher grades of product), toward preventing consumption for all unnecessary purposes and reducing it wherever else possible, and toward confining exports to the essential needs of our allies.

Aids in expanding the domestic output included exploratory work and drilling operations in promising areas by the Geological Survey and Bureau of Mines, liberalization of the lending policy of the Reconstruction Finance Corporation in connection with mine development, plant construction by the Defense Plant Corporation, bonus payments by the Metals Reserve Co. for production over established quotas, and priority assistance of the War Production Board to the undisturbed flow of necessary materials for productive operations.

Digitized by Google

Many of these factors are described in greater length later in this report. On the other side of the picture, reduction in unnecessary consumption was attained principally through orders issued by the War Production Board, at times in cooperation with other agencies. As a result of W. P. B. limitation orders, the use of copper has been discontinued in thousands of civilian products, and the Army, Navy, and Maritime Commission have cooperated by reducing copper requirements for many necessary items. Copper exports are also under strict control. An example of a noteworthy saving of copper is given in the report of the Communications Equipment Division of W. P. B., which states that only about 12,000 tons will be needed in the wire-communications industry for maintenance and operation of the domestic telephone and telegraph networks during 1943. It was estimated that an equal amount of copper in the form of scrap would be returned to the Nation's stock pile by this industry. The companies were said to have used 35,000 tons in 1942 and between 90,000 and 100,000 tons in 1941.

As a result of the conservation measures mentioned, inventories of thousands of tons of copper and copper products were frozen, and the Government arranged to purchase these stocks through the Copper Recovery Corporation, formed in May 1942. A report released in May 1943 stated that the original estimates of idle and excessive copper to be recovered ranged from 400 to 500 million pounds. Thus far, according to the report, 114,000 firms had been approached under the program, and plans were being made to reach 98,000 plumbers, building contractors, and their suppliers. A total of 197 million pounds had been allocated, of which 56 million were sold for use in unchanged form, 93½ million were allocated for remelting, 30 million were directed into the regular scrap markets, and owners were authorized to retain 17 million for essential production.

The Metals Reserve Co. and the Board of Economic Warfare provided for the purchase of available foreign copper, particularly in Western Hemisphere countries; and the Maritime Commission secured all possible shipping facilities, concentrating primarily on providing space for bringing into the country at the least all possible amounts of refined and blister copper.

[1] Includes old tailings.
[2] Figures not yet available.
[3] Data include copper imported for immediate consumption plus material entering country under bond.
[4] Total exports of copper, exclusive of ore, concentrates, composition metal, and unrefined copper. Exclusive also of "Other manufactures of copper," for which figures of quantity not recorded.
[5] Exclusive of bonus payments of the Metals Reserve Co.
[6] Approximate.

Although our total supplies of copper failed by a substantial margin to fill our own total demands, it was imperative that consideration be given to the essential requirements of our Allies; according to Lend-Lease authorities, 7.2 percent of our total new supply (production plus imports) for 1942 was exported.

Another important step in balancing supplies and requirements was the increasing use of substitutes. In this connection, Lt. Gen. Brehon B. Somervell, commanding the Army Service Forces, recently said:

> In the 2 years 1942–43 we shall save 400,000,000 pounds of copper, probably our most precious metal today, by using steel in cartridge cases instead of brass. Nearly 50 producers now are making steel shell cases. In addition, by substitution and other engineering changes, we shall save 75,000,000 pounds of copper * * *.

Because more copper was available for use than ever before, because of the successful efforts to reduce consumption of copper in many ways through curtailing uses and substitution, and because it was almost impossible to accept the fact that even modern warfare could require such enormous quantities of this metal, some observers felt that the copper problems had been solved. In contradiction of this attitude H. O. King, chief of the Copper Branch, War Production Board, said early in 1943:

> Recent statements quoted in the press have conveyed the impression that the supply of copper is adequate to meet all military and essential civilian require-

Digitized by Google

ments. Widespread acceptance of such statements would constitute a threat to our entire war production program. The supply of copper is not adequate and never will be while this war is on. * * *

As we got deeper into war, the Office of War Information determined that it was inadvisable to release information on many raw materials, and both trade and Government statistics were involved. Publication of Bureau of Mines monthly copper mine figures was discontinued following the statement for January 1942. Trade data on smelter and refinery production and stocks, and fabricators' figures on consumption and stocks were not revealed after May. Domestic sales data were not released after June.

In January 1942 the Copper and Zinc Branch of the War Production Board was separated into two branches, and in February, Harry O. King was named to head the Copper Branch. King had previously been in Government service as the division administrator of National Recovery Administration, from which he resigned to become managing director of the Copper Code Authority. A Copper Producers Advisory Committee was formed later, with King as its chairman and the following members from industry: K. C. Brownell, vice president, American Smelting & Refining Co.; Robert E. Dwyer, vice president, Anaconda Copper Mining Co.; Carl T. Ulrich, vice president, Kennecott Copper Corporation; J. F. McClelland, vice president, Phelps Dodge Corporation; A. J. McNab, vice president, Magma Copper Co.; B. N. Zimmer, vice president, American Metal Co.; and A. E. Petermann, vice president, Calumet & Hecla Consolidated Copper Co. Early in 1943 a Combined Copper Committee was set up by the Combined Production and Resources Board and the Combined Raw Materials Board to assemble and review data on supplies and requirements of the United States, the United Kingdom, and Canada in order that available metal be most efficiently utilized. King was made chairman of this committee.

INVESTIGATIONS OF THE BUREAU OF MINES AND GEOLOGICAL SURVEY

Prospecting for copper ores was begun in July 1942, when allotments for exploration projects were made from funds appropriated to the Bureau of Mines for investigation of critical and essential minerals. At the close of the calendar year 1942, 12 exploration projects had been established, involving diamond drilling at 9 deposits, surface trenching at 2, and underground sampling at 1. One project was completed in 1942.

Among results of the prospecting in 1942 were: (1) The establishment of additional reserves of indicated ore at the Elizabeth mine of the Vermont Copper Co., Orange County, Vt., amounting to 300,000 tons averaging over 2 percent copper. Production is expected to begin in March 1943; (2) the discovery of about 75,000 tons of indicated ore containing 2.06 percent copper and 0.3 percent cobalt at the Uncle Sam mine, Blackbird district, Lemhi County, Idaho; (3) the finding of some ore at depth in the Christmas mine, Gila County, Ariz.

In the laboratory, favorable tests were made: (1) To separate tungsten from copper minerals at the Empire mine, Custer County, Idaho; (2) to float selectively copper and cobalt minerals at the Uncle Sam mine, Lemhi County, Idaho; (3) to treat ores from the Hidden Treasure mine, Missoula County, Mont.

Digitized by Google

During the calendar year 1943 the Bureau of Mines plans to continue prospecting at the Elizabeth mine, Uncle Sam mine, and Christmas mine and to explore additional deposits when investigations now in progress are completed. The Bureau also intends to investigate the possibilities for re-treating mill tailings at several plants.

In the latter half of 1942 the Geological Survey greatly expanded its studies of copper deposits, in accordance with its program of investigating deposits of minerals currently needed for war production. Although emphasis was focused on detailed studies in minor districts that offer favorable possibilities for increased production, many brief examinations of individual copper deposits also were made during the year, often at the request of other Government agencies. Geologic investigations were made of copper deposits in the continental United States, Alaska, and several Latin American republics.

At the end of 1942 investigations in the United States were in progress in the Elizabeth mine, Vermont; Michigan; Pastura, N. Mex.; Christmas mine and Old Hat district, Arizona; the Penn mine, California; Glacier Peak, Wash.; Mackay, Idaho; and the Southeastern States. In several of these projects, Survey geologists were collaborating with Bureau of Mines engineers on exploration projects.

In Alaska during the summer of 1942, the Geological Survey investigated nickel-copper deposits at Spirit Mountain (Copper River region), at Mirror Harbor (Chichagof Island), and at Bohemia Basin (Yakobi Island); copper-molybdenum deposits at Orange Hill (Copper River region); iron-copper deposits of the Mount Andrew-Mamie area and the Poorman area (Prince of Wales Island); and copper-palladium deposits at the Salt Chuck mine. Reports on several earlier investigations in Alaska [1] were published during 1942.

In 1942 Survey geologists investigated copper deposits in Cuba and Haiti under the auspices of the Department of State and in Colombia and Central America under the auspices of the Board of Economic Warfare.

RECONSTRUCTION FINANCE CORPORATION LENDING POLICY

The lending policy of the Reconstruction Finance Corporation was liberalized in March to permit the owner or lessee of a mining property to borrow amounts not exceeding $20,000 to defray costs of developing small ore bodies containing strategic and critical metals. The loans were to be obtainable out of R. F. C. funds, repayable out of proceeds from operations; if the initial development showed favorable results, additional loans up to another $20,000 were to be had for further development.

BONUS PAYMENTS

Government action regarding the payment of bonuses to individual producers for production of copper over established quotas, whereby the payments were made by the Metals Reserve Co. and the quotas were assigned by the War Production Board and the Office of Price Administration, was discussed in the Copper chapter of Minerals

Yearbook, 1941. The quotas assigned were said to be so high that there was little chance that larger producers could produce enough copper to benefit. Small, high-cost, and new producers were the immediate beneficiaries. At the same time, the plan was sufficiently flexible so that at any time quotas could be lowered to give greater aid, without affecting the price of copper to consumers. Moreover, the quotas were established by mines or groups of mines rather than by companies, to avoid any possibility that expenditures for expansion of one property might be deterred by uncertainties as to future production from one mine or group of mines of the same company. Many quotas were revised downward during the year. An increasing number of copper quotas were lowered in the last month of the year and into 1943. This action was taken largely to permit copper companies to absorb the additional costs of mining caused by rather general wage increases late in the year. In recognition of the possibility of greater production gained by having an established, satisfactory price over an extended period, the Government in January 1943 extended the premium plan to July 31, 1945. The plan was amended May 1, 1943, to make possible additional premiums for mines that produced less than 2,000 tons of copper in 1942 and which required increased revenue to obtain maximum production. Individual mines were to be studied independently and special premiums to be paid for output over special quotas established. The Metals Reserve Co. announced that royalty payments on production entitled to premium payments would be paid on ceiling prices unless the lease specifically instructed otherwise, as it was not the intent of the order to have anyone other than the actual operator participate in the plan. Royalties paid by domestic mine operators for copper, lead, and zinc ores mined from leased properties were frozen by the Office of Price Administration on April 1, 1943, at rates in effect on December 31, 1942.

LABOR CONDITIONS

The labor situation at mines, mills, smelters, and refineries got progressively worse as the year advanced and reached a low point about August. At that time the War Labor Board was considering action in a large number of nonferrous mine cases which it had promised the miners to expedite. Local draft boards were requested to see that the mining program was not scotched by Army manpower requirements. The International Union of Mine, Mill and Smelter Workers reported that 3,000 men would be required to raise operations to full capacity. Later in the month the War Manpower Commission subjected migrations of lumber and copper workers in 12 Western States (termed a "critical labor area") to United States control. The States were Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Texas, Utah, Washington, and Wyoming. In this area workers could not switch jobs (except under certain specified conditions) or employers release workers without first obtaining certificates of separation from the United States Employment Service. Gold mining was virtually stopped in the hope of inducing workers in those mines to accept employment in strategic metal mines, and the Government furloughed 4,000 men from the Army provided they

Digitized by Google

entered the strategic metal mines, particularly copper mines. The mines were benefited, at least temporarily, by a greater number of employees. Many of the recommended wage increases were accepted by the War Labor Board and subsequently approved by the Director of Economic Stabilization. The increases granted took up only part of the slack between wages in the mining industry and in others, such as airplane factories, shipyards, etc., and the urge to leave mining communities continued to be a deterrent factor in the labor situation.

CONSUMPTION AND DISTRIBUTION CONTROLS

Copper, copper-base alloys, and copper scrap were under complete priority control before the beginning of 1942. The War Production Board issued amendments and revisions to the control orders from time to time throughout 1942. These were directed mostly toward increasing the restrictions on uses. The supply situation became so tight by September that the Army and Navy and the Maritime Commission agreed to rigid restrictions that confined copper consumption to vital war uses. The Production Requirements Plan (PRP) was put into operation in the third quarter of 1942 (it was partly effective beginning the first quarter); its purpose was to provide stricter controls on the distribution of scarce materials. With few exceptions it applied to all concerns using metal valued at $5,000 during a calendar quarter. Manufacturers were asked to estimate their requirements for 3 months in advance. The plan was closely tied in with end-use allocation classification. An intricate system of numerical symbols was provided to identify the ultimate use to which the raw material was to be put. This plan, it was announced in November, was scheduled to give way to the Controlled Materials Plan (CMP) in part in the second quarter of 1943 for aluminum, copper, and carbon and alloy steel, "the three most basic and critical materials," and to be completely superseded by CMP for these products by July 1943. Under PRP each firm, large or small, prime contractor or subcontractor, submitted its own requirements to the War Production Board for approval and received an individual authorization to obtain materials. Under CMP, prime contractors were to prepare and submit a breakdown of all materials required for the approved end-products on which they are working. The break-down was to comprise a "bill of materials" specifying not only what materials were required, but when they must be received to carry out the authorized program. The bills of materials were to include controlled materials required by the prime contractors and their subcontractors and their suppliers and also other scarce materials listed in the outline of the plan. The bills of materials from prime contractors were to be assembled by claimant agencies and presented to the War Production Board Requirements Committee and to the respective Controlled Materials Branches, which were to make the necessary adjustments to bring the whole program into balance with available supplies. The original claimant agencies included the Army, Navy, Maritime Commission, Aircraft Scheduling Unit, Office of Lend-Lease Administration, Board of Economic Warfare, and Office of Civilian Supply, but this list was promptly expanded.

PRICE ACTION

Ceiling prices of the Office of Price Administration for electrolytic and casting copper were discussed in the chapter on Copper in Minerals Yearbook, 1941. The principal price action on copper in 1942 (which, however, did not affect the price to consumers) was the establishment of bonus payments for overquota production, which already have been discussed under that heading. Ceilings for less than carlot shipments were revised in 1942, prices for copper alloy and scrap items not already covered were established by the General Maximum Price Regulation in May 1942 at the levels prevailing in March (many of which were changed by subsequent orders), and the prices to be paid by the Government for copper and copper-base alloy products in inventories frozen by various limitation and conservation orders were selected. Establishment of specifications and cents-per-pound prices for 16 new grades of copper scrap and copper-alloy scrap, effective March 22, 1943, brought under specific prices the entire field of such material when sold to consumers. Ceiling prices on scrap items are discussed in the chapter on Secondary Metals—Nonferrous.

DOMESTIC PRODUCTION

Statistics on copper production may be compiled upon a mine, smelter, or refinery basis. Mine data are most accurate for showing the geographic distribution of production; smelter figures are better for showing the actual recovery of metal and fairly accurate for showing the source of production; and refinery statistics give precise information regarding metal recovery but indicate only in a general way the source of crude materials treated. The chapter on Copper in Mineral Resources of United States, 1930, part 1, discusses the differences among the three sets of figures.

Copper produced from domestic ores, as reported by mines, smelters, and refineries, 1938–42, in short tons

Year	Mine	Smelter	Refinery
1938	557,763	562,328	552,574
1939	728,320	712,675	704,873
1940	878,086	909,084	927,239
1941	958,149	966,072	975,408
1942	1,080,062	1,087,991	1,064,792

PRIMARY COPPER

Smelter production.—The recovery of copper by United States smelters from ores of domestic origin totaled 1,087,991 short tons in 1942—a 13-percent increase over 1941. Domestic smelter output constituted 51 percent of the world production during 1925–29. The proportion dropped sharply in the succeeding years until 1934, when it was only 17 percent. It rose to 32 percent in 1936 and from then until 1939 never fell below 25 percent, fluctuating between the two figures. The proportion was believed to be between 31 and 35 percent in 1940 to 1942 and to be at the top of this range in the latest year.

The figures for smelter production are based upon confidential returns from all smelters handling copper-bearing materials produced in the United States. For Michigan the sum of furnace-refined copper

Digitized by Google

and copper cast into anodes for electrolytic refining is included. The figures for blister represent the fine-copper content. Some casting and electrolytic copper produced direct from ore or matte is included in the smelter production. Metallic and cement copper recovered by leaching is included in smelter production.

The precise quantity, in pounds, of copper produced by smelters in the United States and its value are shown by years for 1845–1930 in the Copper chapter of Mineral Resources of the United States, 1930, part 1.

Copper produced in the United States from domestic ores, 1938–42, by States

[Smelter output, in short tons fine]

State	1938	1939	1940	1941	1942

Copper produced (smelter output) in the United States, 1938–42, and total, 1845–1942

[Values rounded]

Year	Short tons	Value
1938	562,328	$110,216,000
1939	712,675	148,236,000
1940	909,084	205,453,000
1941	966,072	227,993,000
1942	1,087,991	[1] 256,766,000
Total, 1845–1942	29,552,541	8,736,779,000

[1] Excludes bonus payments of Metals Reserve Co.

Mine production.—The figures for mine production are based upon reports supplied to the Bureau of Mines by all domestic mines that produce copper. Details of the method of collecting the statistics and reasons for the discrepancy between mine-, smelter-, and refinery-production figures are given in the Copper chapter of Mineral Resources of the United States, 1930, part 1.

Mine production is more accurate than either refinery or smelter production for showing the distribution of domestic output by States and districts. It also indicates the production by calendar years more

Digitized by Google

exactly, because additional time is required for smelting and refining. Mine production in 1942 was 1,080,062 tons—an increase of 13 percent over that in 1941 and 22 percent above the average for 1925–29.

Production by States and districts.—The following tables show mine and smelter production by States for 1941 and 1942 and mine output by districts for 1938–42. In 1942 Arizona, Utah, and Montana led in production with 78 percent of the smelter total compared with 75 percent in 1941; adding the output of Nevada, New Mexico, and Michigan to the foregoing brings the proportions to 97 percent of the total for the country compared with 96 percent in 1941. Arizona supplied 36 percent compared with 29 percent for Utah and 13 percent for Montana. Montana's share of the total was unchanged from 1941, but the other two States showed gains. The three other most important copper-producing States (Nevada, New Mexico, and Michigan) represented smaller proportions of the country's total in 1942, although all produced more copper than in 1941. Among other States, there were sharp drops in output for Colorado and California. These declines were due to replacement of production of copper-iron-silver-gold ore in favor of zinc-lead ore at the Eagle mine of the New Jersey Zinc Co. in Colorado and closing of the Walker mine in Plumas County, Calif., which left that State without an important copper producer. Comparison of present production with that of the past century shows that Utah's share of the country's total is rising sharply, whereas Arizona's is becoming static at somewhat above the earlier period. Michigan and Montana are dropping markedly, while New Mexico and Nevada are advancing.

Copper produced in the United States, according to smelter and mine returns, by States, 1941–42 and 1845–1942, in short tons

State	1941		1942			1845–1942 smelter output	
			Smelter returns

In 1942 the Bingham (Utah) district experienced no difficulty in maintaining its lead among the copper-producing districts of the country for the seventh consecutive year; its output was 117 percent higher than that of its nearest competitor, the Butte (Mont.) district. For 7 years the Butte district ranked second in production, and its total production from the beginning of operations is far above that of any other district in the country. Following the Globe-Miami district, Ariz., which has ranked third for a number of years, is a group of districts that frequently changes place in importance as copper producers.

Details of mine production, by districts and companies, in 1942 are available in the chapters of this volume dealing with the production of gold, silver, copper, lead, and zinc in the various States.

Mine production of copper in the principal districts of the United States,[1] 1938–42, in terms of recovered copper, in short tons

[1] Districts producing 1,000 short tons or more in any year of the period 1938–42.
[2] Not listed in order of output.
[3] Includes a small quantity produced elsewhere in Alaska.
[4] Negligible.
[5] Bureau of Mines not at liberty to publish figures.

Quantity and estimated recoverable content of copper-bearing ores.—The following tables list the quantity and estimated recoverable copper content of the ore produced by mines in the United States in 1941; figures for 1942 are not yet available. Of the total copper produced from copper ores in the United States in 1941, 85 percent was obtained from ores concentrated before smelting and 10 percent from direct-smelting ores; in addition, copper was recovered from 3,785,654 tons of copper ore treated by straight leaching. The percentages for 1941 compare with 84 percent obtained from concentrated ore and 11 percent from direct-smelting ores in 1940. In 1940, 3,198,904 tons of copper ore were treated by straight leaching.

Close agreement between the output as reported by smelters and the recoverable quantity as reported by mines indicates that the estimated

Digitized by Google

recoverable tenor is close to the actual recovery. Classification of some of the complex western ores is difficult and more or less arbitrary. "Copper ores" include not only those that contain 2.5 percent or more copper but also those that contain less than this percentage if they are valuable chiefly for copper. Mines report considerable copper from ores mined primarily for other metals. These include siliceous gold and silver ores, lead and zinc ores, and pyritic ores.

Copper ore, old tailings, etc., sold or treated in the United States in 1941, with copper, gold, and silver content in terms of recovered metals

State	Ore, old tailings, etc., sold or treated (short tons)	Copper produced		Gold produced (fine ounces)	Silver produced (fine ounces)	Value of gold and silver per ton of ore

[1] Includes old tailings, etc.
[2] Exclusive of Alaska, figures for which Bureau of Mines not at liberty to publish.

REFINERY PRODUCTION

The refinery output of copper in the United States in 1942 was made by 11 plants; 8 of these employed the electrolytic method, 2 the furnace process on Lake Superior copper, and 1 the furnace process on western ores.

There are five large electrolytic refineries on the Atlantic seaboard, three Lake refineries on the Great Lakes, and three electrolytic refineries west of the Great Lakes—one at Great Falls, Mont.; one at Tacoma, Wash.; and one at El Paso, Tex. In 1942, fire-refined copper was produced for the first time at the Hurley plant of the Kennecott Copper Corporation. Of the above plants, the Lake refinery of the Quincy Mining Co. has been idle since 1933.

In addition to the foregoing plants, that at Inspiration, Ariz., is equipped to make electrolytically refined copper direct from the liquors obtained from leaching; this copper is shipped as cathodes to other refineries, where it is melted and cast into merchant shapes.

Digitized by Google

The 13 plants indicated constitute what commonly are termed "regular refineries." Of these plants, 9 employ the electrolytic process and 4 the furnace process. The Phelps Dodge Refining Corporation plant at El Paso used both methods in 1942. The electrolytic plants have a rated capacity of 1,547,000 tons of refined copper a year. As they produced 1,390,000 tons in 1942, this part of the industry was operated at 90 percent of capacity.

The following tables show the production of refined copper at regular refining plants, classified according to source, grade, and form in which cast.

Primary and secondary copper produced by regular refining plants in the United States and imported, 1938–42, in short tons

	1938	1939	1940	1941	1942
Primary:					
Domestic: [1]					
Electrolytic [2]	516,488	662,409	883,610	929,711	963,177
Lake [2]	36,011	42,464	43,629	45,697	46,523
Casting	75				55,092
	552,574	704,873	927,239	975,408	1,064,792
Foreign: [1]					
Electrolytic	239,818	304,642	386,317	419,901	343,834
Casting and best select	24				6,935
Refinery production, new copper	792,416	1,009,515	1,313,556	1,395,309	1,414,561
Imports, refined copper [3]	1,801	16,264	68,337	346,994	395,039
Total new refined copper made available	794,217	1,025,779	1,381,893	1,742,303	1,809,600
Secondary:					
Electrolytic [4]	92,542	116,613	117,669	95,437	83,079
Casting				4,238	2,064
	92,542	116,613	117,669	99,675	85,143
Grand total	886,759	1,142,392	1,499,562	1,841,978	1,894,743

[1] The separation of refined copper into metal of domestic and foreign origin is only approximate, as accurate separation at this stage of manufacture is not possible.
[2] Some copper from Michigan is electrolytically refined at eastern refineries and is included as electrolytic copper.
[3] Data include copper imported for immediate consumption plus material entering country under bond.
[4] Includes some secondary Lake copper.

Copper cast in forms in the United States, 1941–42

Form	1941		1942	
	Short tons	Percent	Short tons	Percent
Wire bars	736,000	49.23	582,000	38.81
Cathodes	300,500	20.10	464,500	30.98
Cakes	191,500	12.81	119,500	7.97
Ingots	128,500	8.60	219,500	14.64
Other forms	138,500	9.26	114,000	7.60
	1,495,000	100.00	1,499,500	100.00

In addition to the regular refineries, numerous plants throughout the country operate on scrap exclusively, producing metallic copper and a great variety of alloys. The output of these plants is not included in the statements of refined-copper production in the preceding tables but is included in the following statement of secondary-copper production.

Digitized by Google

Copper sulfate.—The production of hydrous copper sulfate or bluestone by copper refineries in the United States was 31,704 short tons having a copper content of 8,076 tons in 1942 compared with 27,417 tons having a copper content of 6,984 tons in 1941.

The output of copper sulfate by plants other than the regular primary refineries totaled 72,411 tons with a reported copper content of 18,390 tons in 1942 compared with 58,072 tons containing 14,684 tons of copper in 1941.

Copper chemicals, including copper sulfate, were placed under allocation control in an order effective October 1, 1942. The Office of Price Administration set the ceiling price for copper sulfate at $5 per 100 pounds, effective April 3, 1943, for sales by manufacturers and May 3 for sales by others. Previously the price had been $5.15 in the East and as high as $5.50 in the West. In May the order was amended to permit an increase to $5.15 for deliveries in the West. In an article on insecticide chemical requirements for war food supplies McBride [2] stated that over 200,000,000 pounds of copper chemicals, principally copper sulfate, are wanted for military use, for export, for other industries, and for insecticides. Availability of scrap, he said, would determine the size of production. In 1939 51,122,000 pounds of copper sulfate were used for agricultural purposes, and in the fiscal year ended September 30, 1942, 79,539,000 pounds were so used; 86,000,000 pounds were estimated as requirements for this purpose in 1943.

SECONDARY COPPER

Secondary copper includes material recovered from remelting old copper and copper scrap and from the treatment of copper alloys or alloys treated without separation of the copper. The following table summarizes the production of secondary copper during 1938–42. Further details appear in the chapter on Secondary Metals—Nonferrous.

Secondary copper produced in the United States, 1938–42, in short tons

	1938	1939	1940	1941	1942
Copper recovered as unalloyed copper	192,400	151,370	170,839	135,869	114,647
Copper recovered in alloys	167,400	[1] 348,330	[1] 361,207	[1] 590,527	[1] 813,108
Total secondary copper	359,800	499,700	532,046	726,396	927,755
From new scrap	92,500	212,800	198,156	313,697	500,633
From old scrap	267,300	286,900	333,890	412,699	427,122
Percent of domestic mine output	65	69	61	76	86

[1] Includes copper in chemicals as follows: 1939, 3,200 tons; 1940, 9,431 tons; 1941, 9,804 tons; 1942, 17,455 tons.

CONSUMPTION

Available data on consumption of copper indicate that new high record rates of use were established in 1941 and again in 1942. The calculations were made upon the basis of copper available for use, or apparent consumption. Also, in estimating apparent consumption it has been assumed that copper used in the manufacture of primary

[2] McBride, R. S., Insecticide Chemicals Needed For War Food Supply: Chem. and Met. Eng., vol. 50, No. 3, March 1943, pp. 101–103.

Digitized by Google

fabrications of copper is copper consumed. It is likely that statistics compiled upon a different basis (for example, by taking consumption as including only copper made into automobiles, electrical equipment, ships, etc.) would show very different results. Much copper leaves the country as primary fabrications and considerably more in manufactured products containing copper. Actual consumption data may be compiled at many points in the industrial process. The method of calculating the quantity of copper available for consumption is shown in the following table. It should be noted that exports and stocks include some refined secondary copper that cannot be determined separately and also that actual consumption of new copper would differ from the figures shown in the table by the changes in consumers' stocks.

New refined copper withdrawn from total year's supply on domestic account, 1938–42, in short tons

	1938	1939	1940	1941	1942
Total supply of new copper	794, 217	1, 025, 779	1, 381, 893	1, 742, 303	1, 809, 600
Stock at beginning of year	179, 000	181, 000	95, 500	91, 500	77, 500
Total available supply	973, 217	1, 206, 779	1, 477, 393	1, 833, 803	1, 887, 100
Copper exported [1]	385, 223	396, 406	377, 108	114, 753	132, 467
Stock at end of year	181, 000	95, 500	91, 500	77, 500	84, 000
	566, 223	491, 906	468, 608	192, 253	216, 467
Withdrawn on domestic account	406, 994	714, 873	1, 008, 785	1, 641, 550	1, 670, 633

[1] Includes refined copper in ingots, bars, rods, or other forms.

The usual discussion of consumption of copper by uses cannot be given owing to inability of the American Bureau of Metal Statistics, the source of previous data on this subject, to obtain and release information because of the war.

STOCKS

The following table gives domestic stocks of copper as reported by primary smelting and refining plants. Stocks of blister and anode copper in transit from smelters to refineries are included under blister copper.

Stocks of copper at primary smelting and refining plants in the United States at end of year, 1938–42, in short tons

Year	Refined copper	Blister and materials in process of refining [1]	Year	Refined copper	Blister and materials in process of refining [1]
1938	181, 000	233, 000	1941	77, 500	240, 000
1939	95, 500	260, 000	1942	84, 000	235, 500
1940	91, 500	243, 000			

[1] Includes copper in transit from smelters in the United States to refineries therein.

Digitized by Google

Total inventories of copper in the hands of smelters and primary refineries at the end of 1942 were virtually unchanged from those on hand at the beginning of the year, having gained less than 1 percent; refined stocks rose 8 percent and those of blister and unfinished materials at smelters, in transit to refineries, and at refineries fell 2 percent.

Figures compiled by the Copper Institute (published in the press before June) show that domestic stocks of refined, duty-free copper declined to 65,309 tons at the end of 1942 from 75,564 tons at the end of 1941 and 142,772 tons at the end of 1940. At the end of 1938 refined stocks were more than double those on hand at the end of 1940 and were more than four times those at the end of 1942. There are always differences between the stock data of the Bureau of Mines and those of the Copper Institute, due partly to a somewhat different coverage and partly to an arbitrary but permissible method used by the Copper Institute in designating the copper as domestic or foreign metal. This latter factor causes a time-lag difference between the two sets of figures.

According to fabricators' statistics (also published in the press before June), there were large variations in their inventories in recent years. Stocks of refined metal, in-process material, and primary fabricated shapes totaled 339,376 tons at the end of 1940, declined to 295,813 tons at the end of 1941, and rose to 414,668 tons at the end of 1942. Meanwhile unfilled purchases of refined copper in fabricators' hands fell from 326,269 tons at the end of 1940 to 241,335 tons at the end of 1941 and to 135,481 tons at the close of 1942. Fabricators' working stocks, which rise and fall according to plant activity, were 240,740, 291,515, and 340,547 tons, respectively. Unfilled sales by fabricators to customers rose from 414,892 to 547,468 to 613,005 tons. Even the staggering figure of 613,005 tons at the end of 1942 marked a decline from the historic total of 689,177 tons at the end of June. Copper classed as "available for sale" was 10,013 tons at the end of 1940, and —304,675 and —403,403 tons, respectively, at the close of 1941 and 1942.

The quantity of copper delivered thus far to the Metals Reserve Co. aggregates the equivalent of more than a good year's production from domestic mines. Monthly allocations are made against these stocks, and at the end of 1942 only 15 percent of the total metal delivered remained in the stock pile.

PRICES

Reports to the Bureau of Mines from copper-selling agencies indicate that 1,086,000 tons of copper were delivered to domestic and foreign purchasers (excluding deliveries of foreign copper to the Metals Reserve Co.) in 1942 at an average price (f. o. b. refinery) of 11.8 cents a pound, unchanged from 1941 and 0.5 cent a pound higher than in 1940. The average price for 1942 is exclusive of bonuses paid for the overquota outputs of individual mines. Such bonuses are described later. Bonus payments added between 0.3 and 0.4 cent a pound to the average realization for copper in 1942, but only a relatively small proportion of total production benefited and that which did received 5 cents a pound above the ceiling price.

Ceiling prices were placed on electrolytic and casting copper in 1941 and were described in the chapter of Minerals Yearbook, 1941, on this subject. In January 1942 the Metals Reserve Co. was authorized to buy copper produced at domestic mines, and fulfilling certain requirements, at 5 cents above the ceiling price, or at 17 cents a pound. Payments were to be made on production from February 1, 1942, and were to extend over 2½ years. The payments were to be made only on production over quotas set by the War Production Board and the Office of Price Administration. The plan was inaugurated to stimulate production from either new or high-cost properties, or both. When individual quotas were established the mines falling into preferred classes were found largely to have zero quotas, which entitled the total amounts produced to bonuses. Well-established, large properties were assigned such high quotas that they were entitled to virtually no benefits. It was necessary during the year to revise a number of quotas to eliminate inequities. Late in the year and early in 1943 it became desirable to revise downward many more to take care of the generally increased costs of production. In January 1943 the plan was extended to July 31, 1945. On May 1, 1943, it was an-

Digitized by Google

nounced that a special additional premium would be made available to small copper mines that produced less than 2,000 tons of copper in 1942 and required increased revenue to obtain maximum production. Individual cases were to be considered separately, and a special premium was to be paid at a rate to be fixed for each mine on production in excess of a special quota. Premiums and quotas were subject to adjustments at any time or revocation on 30 days' notice.

The premiums for less-than-carlots sold by producers and refiners were revised in January 1942, effective February 1. The ceiling prices l. c. l. on electrolytic, Lake, and other fire-refined copper and casting copper were set at 12⅛ cents and 12 cents per pound f. o. b. shipping points, respectively. Premiums were no longer permitted on casting copper sold by persons other than a producer or refiner.

Copper and copper-alloy scrap prices are discussed in the chapter on Secondary Metals—Nonferrous.

The following official maximum prices, delivered to consumers' plants, have prevailed in the London market since December 18, 1939:

	Per long ton		
	£	s.	d.
Electrolytic, high conductivity	62	--	--
Fire-refined:			
High conductivity	62	--	--
High grade	61	10	--
Minimum, 99.7 percent	61	--	--
Minimum, 99.2 percent	60	10	--
Hot-rolled black wire rods	65	10	--

FOREIGN TRADE [3]

Under ordinary circumstances, excess copper smelting and refining capacities in the United States are utilized to reduce crude materials from abroad which later are shipped from the country as refined copper or fabricated shapes. This business has been done mainly without the payment of the duty, or if the duty was paid and the copper was subsequently exported virtually all of the expenditure has been refunded. The conditions once considered normal, however, have disappeared. First of all, war demands have, temporarily at least, removed all excess capacity, and all the copper that can be obtained at home or abroad is urgently needed. Copper in refined form (primarily that from Chile), which used to go directly to Europe and which was temporarily stranded without adequate outlet after war was declared, was later welcomed in the United States. Every effort was made to supply adequate shipping tonnage to obtain every available pound of refined metal—an "about face" from the pre-war situation. As a consequence, imports of refined metal reached new heights in 1941 and again in 1942. Since the war started, receipts of copper have been largely from countries that furnished the principal amounts of crude copper before, but, as already stated, the accent has shifted to obtaining higher grades. One important defection is noted in the absence of the usual copper from Yugoslavia. There has been an even greater disruption of export movements. The large shipments to most European countries and to Japan, previously the

[3] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Digitized by Google

principal destinations, have ceased. The United Kingdom is the one exception, as it now leads as a destination of copper from the United States and was one of the leading countries for many earlier years; the U. S. S. R. has taken large amounts, beginning in 1939. Copper is exported now only after careful scrutiny of the requests made and careful weighing of one need against another. Domestic requirements may go unfilled in favor of more urgent ones of our allies. Exports in 1941 and 1942 compared unfavorably with most other years in the twentieth century, and it was expedient that they did so. A noteworthy movement in 1942 was the shipment of over 32,000 tons of copper wire to the U. S. S. R., of nearly 13,000 tons to Egypt, and of nearly 8,000 tons to India. The export movement would be found to have been much larger than is evident from the records for refined and primary manufactures shown in this report, if data on the amounts of copper exported in such manufactured products as airplanes, tanks, and electrical apparatus were available separately.

IMPORTS

As regards imports, the outstanding development of the past 2 years has been the increased receipt of refined copper to record-breaking proportions. This class of imports had little significance from the time the 4-cent tariff on copper went into effect in 1932 to the beginning of the present war. Refined copper began to reach the country in increasing quantities again in 1940, and imports were larger than ever before in 1941 and again in 1942. Since 1932 Chile has furnished virtually all of the refined copper entered, and it has come from mines controlled by nationals of the United States. Canada was an important contributor before that time. In both 1941 and 1942 Chile supplied 99 percent of the total refined copper imported. Because of the absence of sufficient shipping accommodations to bring all desired commodities into the country, there were declines in the receipts of some of the lower grades of copper in 1942 as compared with 1941 and 1940, although most grades compared favorably with other recent years before World War II. Receipts of copper classed by the Department of Commerce as "unrefined black blister and converter copper in pigs or converter bars" were mainly from Chile, Mexico, Belgian Congo, Peru, Canada, and British Africa in 1941 and 1942. Chile supplied less of this grade of copper in 1941 than in 1940 and fell again in 1942. Peru followed the same pattern, and Canada sent only about a fourth as much in 1942 as in either 1941 or 1940. Mexico gained in 1941 and again in 1942, and Belgian Congo, whereas furnishing less in 1942 than in 1941, supplied considerably more in both years than in 1940. Belgian Congo also sent generous amounts of regulus or black copper, being the outstanding supplier of this grade. Imports from Belgian Congo in 1941 and 1942 were largely earmarked for reshipment to the United Kingdom after refining. Imports of the lower-grade classes of concentrates and ores came mainly from Canada, Cuba, Chile, and other Western Hemisphere sources in 1942, and Western Hemisphere sources predominated likewise in 1941. Canada was well ahead of all others in shipping copper concentrates; receipt from this source and from Mexico make no strain on ocean shipping facilities. A noteworthy quantity of copper in concentrates was shipped from the Philippine Islands in 1941. Unfortunately, the resources of these islands added to Japan's supplies in 1942.

EXPORTS

Total exports of copper in 1942, including those of the primary steps of manufacture, were over a third larger than the extremely low total for 1941. Of our principal pre-war customers—Japan, Germany, the United Kingdom, Italy, France, Belgium, and Sweden—only the United Kingdom remains. Three of these countries are our enemies in the present conflict, two are under enemy domination, and the sixth is an uneasy neutral surrounded by shipping and other complications. It is a sad commentary that Japan received nearly 22,000 tons of copper from the United States in 1941. The United Kingdom sharply increased its orders for copper in 1942 and took more of the refined class—the principal one—than it has since 1918. The U. S. S. R., a negligible buyer before the war, received the second-largest quantity of copper shipped from the United States in 1942. The recent sharp gains in shipments of insulated and other copper wire and cable to U. S. S. R., Egypt, and India (British) are worthy of note. In 1942 over 32,000 tons were shipped to the U. S. S. R., nearly 13,000 to Egypt, and nearly 8,000 to India.

The following table gives the destinations of exports of copper and primary manufactures in 1941 and 1942. The chapter on Copper from Minerals Yearbook, 1941, contains a table showing exports by countries for 1937 to 1940 and indicating the revolution in flow of copper from the United States since the outbreak of war in Europe.

WORLD ASPECTS OF COPPER INDUSTRY

Figures on production of copper—and for that matter on all other materials—have not been available for many countries since or immediately before the outbreak of World War II. Copper is one commodity of which the United Nations retain a preponderant share of the world total, however, and upon the basis of available information it is safe to assume that more copper was produced in the world in

Digitized by Google

1942 than in any previous year. The world's largest sources—the United States, Chile, Canada, Northern Rhodesia, and Belgian Congo—were producing at record or near-record levels, and copper from these countries (and from others as well) was all directed toward filling United Nations needs. Nevertheless, the United Nations had insufficient supplies to take care of their expanded war demands for military and essential civilian requirements. Certainly the Axis Powers, much less favored with reference to copper, at least, were hard-pressed to make ends meet. The overrunning of neighboring countries in Europe by the Germans and Italians added principally Yugoslav copper as new supplies. Much copper was also gained by seizing inventories of metal in the conquered territory and from intensive scrap drives therein. The yield in copper and copper products from conquered nations other than Yugoslavia is not of a nature to continue, however, and the situation as regards copper, therefore, must be rapidly worsening. Likewise Japan, despite great gains in raw material supplies, did not succeed in acquiring areas that can yield appreciable quantities of copper. The production of the Philippine Islands was the principal and doubtless only gain in this regard, and under 10,000 tons of copper probably will be obtained annually from that source. Unlike Germany, Japan did not conquer territory that would yield noteworthy quantities of copper, copper alloy, and scrap stocks.

[1] Copper content of blister produced.
[2] Data not available.
[3] Smelter output from domestic and foreign ores, exclusive of scrap. Production from domestic ores only, exclusive of scrap, was as follows: 1939, 646,524 tons; 1940, 824,703 tons; 1941, 876,401 tons; 1942, 987,004 tons.
[4] Copper content of exports.
[5] Figures represent blister copper only. In addition to blister copper, Belgium reports a large output of refined copper which is not included above as it is believed produced principally from crude copper from Belgian Congo and would therefore duplicate output reported under the latter country.
[6] Approximate production.
[7] Estimate included in total.
[8] According to Yearbook of American Bureau of Metal Statistics.
[9] Exclusive of material from scrap.
[10] Output from U. S. S. R. in Asia included under U. S. S. R. in Europe.
[11] Smelter product.
[12] Exports of ingots and slabs.
[13] Less than 1 ton.
[14] January to August, inclusive.
[15] January to October, inclusive.

REVIEW BY COUNTRIES

Australia.—The efforts to augment production in Australia were extended in 1942. Figures showing results of these efforts are not available for the mines. As labor shortages were prevalent and difficulties were experienced in obtaining needed supplies and equipment, it may well follow that production did not gain as expected in 1942. The Government granted a further advance in price from £A86 10s. to £A105 a ton. The basic price to producers for their normal output was to be £A100, with a bonus of £A5 for each ton in excess.

In November it was reported that large-scale mining of copper ore had begun at the Mount Isa mine, Queensland. The stripping of overburden at the Mount Morgan mine was reaching a stage that should permit mining of a greater tonnage of ore. Here open-cut operations to the 700-foot level were in prospect. Ore from the Mount Chalmers mine is to be transported to Mount Morgan for reduction when production begins. In the year ended September 30, 1942, a larger tonnage of ore was treated at the Mount Lyell mine, Tasmania, than in the previous year, but the average grade was lower and only a small increase in the output of copper resulted. Ore reserves at Mount Lyell were given as 14,850,000 tons of ore, averaging 1.14 percent copper, 0.07 ounce silver, and 0.012 ounce gold. Preliminary surface inspection, for the Government, of South Australia mines, idle for many years, and examination of previous records for the district led to the conclusion that absence of sufficient ore in any one section to permit working from one shaft prevented the revival of mining. The report stated that unless geophysical surveying, in conjunction with diamond drilling, can locate new ore bodies worth developing, it is not feasible to work the ore remaining in the mines at Moonta and Kadina. A diamond-drilling program was suggested.

Belgian Congo.—Following a visit of several months in Belgian Congo, the Belgian Minister of Colonies stated that the colony was producing at the rate of about 160,000 tons of copper annually and could add 30,000 tons if new equipment were available. Late in 1942 a reliable authority estimated that 168,000 metric tons would be produced in 1942. The estimated production capacity is reported as 200,000 tons. In the first part of 1943 an extreme drought lasting several months threatened a 20,000-ton drop in the production rate, with a more serious drop in prospect if enough coal could not be obtained from Northern Rhodesia for the steam power plant. A booklet prepared by the Belgian Information Office stated that under purchase agreements with the United Kingdom a minimum of 124,000 English (126,000 metric) tons was to be purchased in 1941 and a minimum of 144,000 long (146,000 metric) tons in 1942. These figures were contrasted with the 3,766 long (3,826 metric) tons imported into the United Kingdom from Belgian Congo in 1914 and 13,178 long (13,390 metric) in 1916. Large amounts of Belgian Congo copper began to come to the United States again in 1940 following a lull of a number of years. In 1941 the United States received 41,300 metric tons of regulus, black or coarse copper, and cement copper and 33,100 tons of unrefined black blister and converter from Belgian Congo, compared with 56,700 tons and 26,400 tons, respectively, in 1942.

Digitized by Google

Bolivia.—Early in 1942 a contract was entered into with the Metals Reserve Co. for the sale of all copper produced to that organization, on the same basis as the one covering Chilean copper and other items. Exports in 1942 aggregated 6,376 metric tons compared with 7,274 tons in 1941.

Canada.—Contrary to expectations and to forecasts in the press, the production of copper in Canada did not establish new peak records in 1941 and 1942. Figures for 1940 recently made available indicate that the peak rate was established in that year, with a mine total of 327,797 short tons; the total for 1941 was 321,658 short tons, and for 1942, 302,690 tons. There is little doubt that successive record outputs would have been made as expected if it had not been for labor difficulties, such as those in the United States.

The Bureau of Mines, Ottawa, summarized the copper operations in Canada recently.[4] That organization stated that Canada's output of copper is obtained from the copper-nickel ores of Sudbury, Ontario; the copper-gold, copper-zinc, and copper-pyrites ores of western Quebec; the copper-zinc ores of northern Manitoba; and the copper ores of British Columbia.

The Britannia Mining & Smelting Co. operated its mine and concentrator at Britannia Beach, British Columbia, shipping the copper concentrate as previously to Tacoma, Wash. A reduction of approximately 50 percent in operations in 1942 was due to labor shortage. The production of Granby Consolidated Mining, Smelting & Power Co. approximated 86 percent of that in 1941. Ore reserves once more gained during the year. Anyox Metals, Ltd., is conducting a diamond-drilling campaign at the Hidden Creek and adjoining properties near Anyox.

Preparations were under way for operation of the Tyee zinc-lead-copper property near Chemainus, Vancouver Island, by Twin "J" Mines, Ltd., under supervision of Wartime Metals Corporation, Canadian counterpart of the Metals Reserve Co. of the United States. Production is expected early in the summer of 1943.

At Flin Flon, Manitoba, Hudson Bay Mining & Smelting Co., Ltd., operated its mine, concentrator, smelter, and zinc plant at increased capacity. A fifth copper roaster was installed and put in operation, and the reverberatory furnace was enlarged. This company is said to have proved an important copper-zinc ore body at Schist Lake by exploratory work. A subsidiary company is equipping the old Mandy mine with a 200-ton concentrating plant, ending many years of idleness at this property, and production is expected in the first half of 1943. Sherritt Gordon Mines, Ltd., has indicated a large tonnage of low-grade copper ore by diamond drilling in a section of its property north of the main ore body. The company mine and mill were operated at capacity.

The leading producer in Ontario, as usual, was the International Nickel Co. of Canada, Ltd., which operated its Frood, Frood Open Pit, Creighton, Levack, and Garson mines and started sinking operations at the Murray and Stobie mines. The concentrator at Copper Cliff was operated at capacity, and the capacity was increased to treat additional tonnages of ore from the Open Pit mining operations. Falconbridge Nickel Mines, Ltd., operated its mine and smelter at

[4] Canada Bureau of Mines, Canadian Copper Operations in 1942 Reviewed: Quoted in the Northern Miner, vol. 29, No. 7, May 6, 1943, p. 20.

Digitized by Google

capacity. The capacity of the smelting plant was increased. Kam-Kotia Porcupine Mines, Ltd., a project of Wartime Metals Corporation, is opening the Jamieson copper property in Robb Township, 20 miles northeast of Timmins.

Metals Controller Geo. C. Bateman of Canada stated that the United States was aiding mining in Canada, that 17 properties were being operated, and that production plans called for the recovery of 46,000 tons of copper.

Chile.—In an effort to supply a substantial part of the needs of the United States Government for copper to feed its war machine, Chile again pushed its copper-production rate into new high territory. Output totaled 477,733 metric tons compared with the previous record tonnage of 453,594 tons in 1941, and the country safely maintained its place as the second most important producer in the world. The Metals Reserve Co. contracted to purchase all of Chile's output. Despite efforts of various United States Government agencies to give all possible help toward increasing the output from Chilean mines, impediments to satisfactory operation were numerous. These involved inadequate supplies of machinery and fuel and scarcity of competent technical personnel. It probably affected small operations more seriously than large ones. The predominant copper-producing mines at Chuquicamata, Potrerillos, and Sewell maintained a high level of activity throughout the year. The Chile Exploration Co. produced 47.25 percent of the country's total, Andes 19.17 percent, and Braden 30.76 percent. Smaller producing mines in Central Chile (according to the Annual Review number of the Engineering and Mining Journal, February 1943) included the Tocopilla, with mills at Tocopilla (300 tons) and Ovalle (700 tons); Ojancos, at Copiapó; and Farellon Sanchez, Merceditas, Volcan, and Carlota, in the Maipo Valley near Santiago. The Chagres and Naltagua smelters operated at capacity; the former handled concentrates produced in the El Cobre and Caracoles mills and the latter received the production of the 500-ton Disputada mill. The Punitaqui mine near Ovalle treated auriferous copper ore in a 400-ton selective flotation plant. A new company was formed to exploit the Cerro Negro mine, 40 km. from Cabildo, Province of Aconcagua; the Compagnie Minière du M'Zaita is ready to exploit the Cerrado mine; and the Carrizal Consolidated has combined the mining claims of Carrizal under one controlling interest. The Caja de Credito Minero was expected to blow in a matte furnace at Carrizal in March.

At the request of the United States Government the Chile Exploration Co. is expanding and enlarging the mining and treatment facilities for copper production at Chuquicamata to increase its output substantially. The project involves the expenditure of about $5,000,000, to be advanced by the Defense Plant Corporation; the advance is to be retired as the copper produced from the additional facilities is sold.

Of the copper exported, the United States received by far the largest amounts. Copper exported as electrolytic copper totaled 264,481 metric tons, of which the United States was the destination of 238,762 tons, Brazil 15,197, and Argentina 10,221. Standard copper exports were 233,763 tons, of which 229,401 were for the United States and 3,732 for Uruguay. The United States was scheduled to receive all of the 14,176 tons of concentrates and the 1,969 tons of ore shipped from the country.

Digitized by Google

Ecuador.—According to the Annual Report of Commerce and Industries for 1942, toward the latter part of the year copper was being exported from the country in the form of blister copper instead of as concentrates. Exports for the year were given as 417 metric tons of copper in bars and 7,407 tons of copper concentrates.

Finland.—The Metal Bulletin (London) of July 17, 1942, stated that the Outokumpu Copper Co., overwhelmingly the principal producer in the country, produced 18,000 metric tons of copper in 1941 and that Finland suffered a severe shortage in this metal despite the fact that normal consumption is only 7,000 tons annually. The shortage resulted from the retention of only 3,000 to 4,000 tons of the total for home consumption. Obviously, with domestic consumption needs unfilled, there must have been urgent reasons for shipment of such a large portion of the total out of the country. Germany is believed to have been the destination of the shipments.

Germany.—Speculation increases as to how Germany's inaccessibility to adequate copper supplies is being overcome as war progresses, and the time factor—from a copper viewpoint at the very least—moves to Hitler's disadvantage. Copper is one of the commodities of which the United Nations control by far the preponderant share, and even the United Nations promptly felt a pinch in regard to its supplies. The Metal Bulletin (London) of December 15, 1942, makes the following suggestions as to how Germany's problem has been managed thus far.

(*a*) She started off with large supplies of manufactured copper and brass components accumulated while the rest of the world was still blissfully anticipating peace, (*b*) she also held considerable stocks of raw copper at the outbreak of war previously sold to her by her future enemies, (*c*) she captured appreciable stocks of virgin copper when she successfully overran various neighboring countries, (*d*) she has stripped most of Europe of all kinds of copper articles, (*e*) she has to some extent offset her lack of copper by substituting aluminum, zinc, plastics, etc.

The partial solution under "(*d*)" is surely not an entirely satisfactory one. Increasing amounts of scrap materials are used ordinarily by both participants in the progress of a war. With Germany, however, the proportion of scrap used must necessarily be larger than in the United Nations. The increased consumption of scrap materials containing a wide variety of metals in widely varying proportions presents metallurgical problems that tend to reduce maximum efficiency and capacity output. No new statistical data can be added to those presented in earlier Minerals Yearbook chapters on Copper.

Mexico.—Mine output of copper in Mexico has gained in the past 2 years; 51,379 metric tons were produced in 1942 and 48,716 in 1941. Both years were above the records for previous years since 1931, though much below the annual average of 61,700 tons for 1923–31. No doubt the improved rate in 1942 is due in part to agreements between Mexico and the United States, signed in April, whereby the Metals Reserve Co. was to purchase, for the period of the agreement, copper and other metals at prices that were expected to stimulate increased production. Under this agreement the Mexican Government assures the mining industry of a stabilized tax policy, no increases in railroad rates on mineral products, and cooperation in other ways to facilitate increased production. The Mexican Government and the Mexican Mining Labor organizations also gave assurances of a cooperative and liberal attitude in applying labor laws and regulations applying to certain phases of mining operations.

At the request of the United States Government, The Cananea Consolidated Copper Co., South America, a subsidiary of Greene Cananea Copper Co., is developing an extensive body of low-grade copper ore adjacent to its present mine and plant at Cananea, Sonora. The company is constructing treatment facilities, involving an expenditure of approximately $12,000,000, designed to increase the production of copper substantially. The construction will be financed through the Metals Reserve Co.

The Moctezuma Copper Co. has entered a contract with the Metals Reserve Co. under which the Pilares mine is to be unwatered to the 2,100 level so that the lower levels can be reconditioned and production increased. Under the contract, Metals Reserve is paying the cost of that work, the cost of operating all the properties of the Moctezuma Copper Co., and a small operating profit and receives the copper produced.

Early in 1943 operations of the Boleo Copper Co. in Lower California were facing possible curtailment owing to difficulties in procuring operating supplies.

Northern Rhodesia.—The supposition that Northern Rhodesia was continuing to break production records, mentioned in Minerals Yearbook, 1941, was not borne out by confidential data made available early in 1943. These showed that the production of 245,622 metric (241,744 long) tons for 1941 was down somewhat from the record of 254,904 metric (250,879 long) tons in 1938 and that the output of 254,654 metric (250,634 long) tons in 1942 just about equaled that for 1938. The details, by mines, for 1941 and 1942 were as follows:

	1941	1942
	(Long tons)	
Mufulira	87,791	84,512
Nchanga	15,804	13,523
Nkana	66,741	82,801
Roan Antelope	71,408	69,798

In a report covering mineral resources of this area, the Mineral Resources Department of the Imperial Institute,[5] London, gives the following information on copper:

The Copperbelt of Northern Rhodesia is an area some 50 miles long and 25 miles wide along the upper reaches of the Kafue river, close to the Katanga border of the Belgian Congo. Several copper deposits are known outside this area, * * * but they are insignificant in size when compared with those of the Copperbelt and none of them is now worked. Natives and Arabs had worked copper at Luanshya and Bwana Mkubwa before the arrival of Europeans whose attentions were therefore soon attracted to these deposits. Development work commenced at Bwana Mkubwa in 1903 and ten years later copper concentrates were exported from the mine. The ores, however, were of relatively low grade compared with those mined profitably in the Katanga, and being oxidized proved difficult to treat, so that when thick deposits of clean sulfide ores averaging 4 per cent of copper were found at Luanshya in 1925 interest in the oxidized ores dwindled. The Luanshya discovery led to the opening up of the Roan Antelope mine, and intense prospecting and geological work followed by drilling soon proved the existence of several enormous sulfide ore bodies in other parts of the Copperbelt. Despite the set-back caused by the world economic depression, copper smelting began at Roan Antelope in 1931, at Nkana in 1932, and at Mufulira in 1937.

The ore deposits occur in synclinal areas in the lower beds of the Mine Series and are generally considered to be of epigenetic origin and related to the intrusion of the Younger Granites, although a syngenetic theory of origin has also been advanced. The ores consist of altered shales and felspathic sandstones containing finely disseminated sulfides, principally chalcocite, bornite, and chalcopyrite.

[5] Imperial Institute Bulletin, vol. 40, No. 4, October-December 1942, pp. 298-301.

Digitized by Google

Most of the deposits consist entirely of sulfides, but the Nchanga ore body contains mixed sulphide and oxidized ores and the Nchanga Extension is largely oxidized ore, malachite being the principal mineral. The ore bodies are sharply defined, gradation into the country rock being exceptional. In form the deposits are beds, usually steeply inclined, and frequently 25 or 30 feet in thickness, but in the Mufulira mine three beds up to 60 feet in thickness occur, and in places two coalesce to form a bed 100 feet thick. The proved reserves of the larger deposits in June 1939, were as follows, taken in order from south to north.

	Reserves (long tons)	*Percent of copper*
Roan Antelope	98, 595, 000	3. 43
Baluba	19, 000, 000	3. 47
Nkana and Mindola	101, 792, 000	3. 43
Chambishi	22, 000, 000	3. 46
Mufulira	96, 800, 000	4. 39
Nchanga	128, 375, 000	[1] 4. 66

[1] 2.53 percent present in oxide minerals and 2.13 present in sulfide minerals.

Further reserves exist which have not yet been proved, and according to the Commissioner of Mines it is probably safe to say that there are at least 750 million tons of high-grade copper ore in the Territory. The proved reserves are greater than those of any other country and the ores are richer than those of the major copper producers, but the annual output of copper is still exceeded by that of the United States, Chile, and Canada.

The producing mines are evenly spaced through the Copperbelt, the Roan Antelope mine at Luanshya in the south, the Nkana mine 21 miles to the northwest, the Mufulira mine 20 miles north of Nkana, and Nchanga, where a pilot mill commenced production in 1939, 29 miles northwest of Nkana. Shafts have also been sunk at the Chambishi mine between Nkana and Nchanga. The Bwana Mkubwa deposit at the southeast corner of the Copperbelt was found to have relatively small ore reserves. A special ammonia leaching process was necessary to treat the ore but, although more than 20,000 tons of copper were thus produced between 1926 and 1930, the process was abandoned and the plant has been dismantled. Each mine has its own smelter producing extremely pure blister copper, and at Nkana there is an electrolytic refinery. From the start of smelting in 1931 until the outbreak of the present war, however, copper production was restricted for economic reasons by agreements with other major copper producers of the world. Between 1936 and 1939 the copper production of the different mines was as follows:

	1936	1937	1938	1939
Nkana, electrolytic copper	28, 012	30, 740	31, 367	29, 654
Nkana, blister copper	28, 092	54, 475	49, 514	50, 126

The article also contains limited descriptions of other copper occurrences in Northern Rhodesia.

Peru.—Recovery of copper from ores produced in Peru showed little change in 1942 from the previous year; production aggregated 37,000 metric tons (preliminary figures) compared with 36,822 tons in 1941. There is little expectation that a noteworthy increase in production will take place in 1943, the continuation of the 1942 rate even being dependent on the maintenance of a reasonable flow of supplies and equipment from the United States. The best chance for enlarged production is said to be at the Yauricocha mine of the principal company, the Cerro de Pasco Copper Corporation, but such an increase would depend on the receipt of equipment additional to that mentioned previously. The output of the principal mines in 1941 and 1942 is shown in the following table.

Copper produced by the principal mines in Peru, 1941–42

Company	1941			1942 [1]		
	Concentrates or ores (metric tons)	Copper		Concentrates or ores (metric tons)	Copper

[1] Preliminary. [2] Cement copper.

The above companies produce roughly 90 percent of the total.

Sweden.—According to reports, the Boliden Mining Co., outstanding producer in the country, is planning to increase its copper production to 18,000 metric tons annually, over double the 1938 rate. Iron pyrites, copper, and zinc have been found in the company mines at Langsele, but so far no mining has been started. Ores rich in iron pyrites and having a low copper content have been discovered and surveyed at Asen and Svansele, but no mining has been done. At Bjurfors the company is mining copper pyrites; the annual production is about 70,000 tons. The company also operates the Laver copper mine near Alvabyn in the Province of Norrbotten, from which copper concentrates are transported by truck and railway to the Rönnskär smelter. At Kristineberg, in the Skellefte district, about 430,000 tons of crude sulfide ore are mined annually, from which copper, zinc, and pyrite concentrates are obtained. Efforts to increase domestic production of copper from ores and scrap materials are believed to have left Swedish supplies notably below consumption requirements.

GENERAL SUMMARY

Record-breaking receipts of foreign lead in 1942 coupled with a fairly steady rate of domestic production, accomplished despite rising costs, eased the supply situation which was outstanding in comparison with other strategic materials and completely reversed the 1941 position relative to supply versus demand. The growing availability of lead under Government control measures permitted partial relaxation of these measures; this allowed increased use of the metal as a substitute for more critical materials, principally copper and zinc, that have a more direct military application than lead.

The production of refined primary lead from domestic and foreign ores decreased less than 1 percent in 1942, the over-all total from both sources being only 4,128 tons less than the 1941 output. Although consumption of refined soft lead was less in 1942, it exceeded domestic production but permitted most of the imports of metal to be retained in the Government stock pile which at the end of 1942 was 13 times as large as at the beginning. Year-end stocks at domestic refineries advanced and reversed a 7-year downward trend, but consumers' inventories were 22 percent lower owing to the nonrelease of enough foreign metal to balance the deficient supply from domestic refineries.

Total imports of lead in all forms during 1942 again broke all records largely because of a 35-percent increase in receipts of refined lead over 1941; more than half of the increase came from Mexico and the balance almost entirely from Australia, Canada, and Peru.

The established price of 5.85 cents a pound for lead at New York at the beginning of 1942 advanced to 6.50 cents on January 13, at which level it remained during the balance of the year; the average price for the year increased from 5.79 cents in 1941 to 6.48 cents in 1942.

[1] This report deals primarily with the smelting, refining, and consuming phases of the industry. For details of mining operations see separate reports issued for the various States.

[1] Data include lead imported for immediate consumption plus material entering the country under bond.
[2] Includes 25,324 tons of foreign refined lead re-exported, according to American Bureau of Metal Statistics; official figures not available.
[3] Includes 3,874 tons of foreign lead re-exported, according to records of the Department of Commerce.
[4] Data not available.
[5] Average for 8 months; London Metal Exchange dealings suspended for duration of war.
[6] Official maximum price fixed by British Ministry of Supply at £25 per long ton.

Figure 1 shows trends in the domestic lead industry since 1900.

War agency regulations.—Throughout 1942 lead remained under full priority control according to General Preference Order M–38 originally announced in October 1941 and later extended beyond the March 1942 termination date. The order provided for a system of allocation that previously had been restricted to releases of foreign lead purchased and held by the Metals Reserve Co., and a "pooling" arrangement was set up whereby primary producers set aside 15 percent of current output each month for allocation to meet special needs. The subsequent easing of the lead situation eliminated the need for this plan later in 1942, and the emergency 15-percent "pool" was dropped after July until further notice, according to Supplementary Order M–38–j effective July 4.

Under Conservation Order M–38–c, issued January 10, 1942, uses of lead were divided into three classes: A prohibited list, an unlimited list, and all other uses limited to 90 percent of the 1941 consumption in each. In September 1942 when the shortage was less acute industry requested some modification of the conservation order, but not until November 11, 1942, and again on January 1, and again on February 2, 1943, were amendments to the order issued that somewhat liberalized the use of lead for construction purposes and as a substitute for more critical materials, such as tin, brass, and bronze. Likewise, Limitation Order L–180, affecting storage batteries, was amended January 5, 1943, to balance consumption with available production of antimonial lead. Despite the continued requests for freer use of lead, further liberalization of the conservation program is limited by the orders and conservation measures that affect other more critical metals.

Digitized by Google

In an effort to stimulate domestic mine production the Office of Production Management, jointly with the Office of Price Administration, on January 13, 1942, announced the details of a premium-price plan whereby producers (miners) of lead (copper and zinc were also included in the plan) received, through the Metals Reserve Co., 9.25 cents a pound for lead produced in excess of quotas based on 1941 output as against the ceiling price of 6.50 cents a pound, New York, established on the same date. This plan, effective February 1, 1942, covered a period of 2½ years. In the Tri-State district a premium of $39.60 (later adjusted to $41.80) per ton for 80-percent lead sulfide

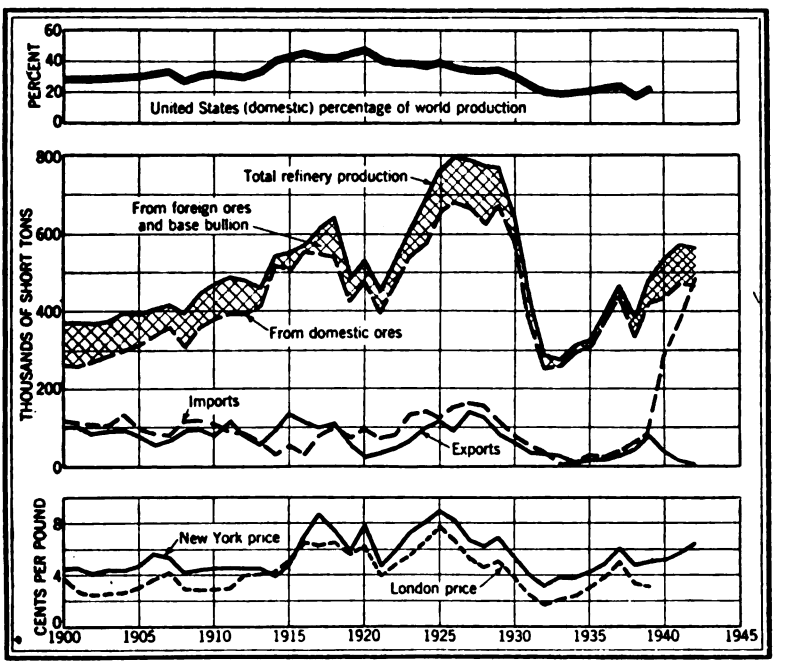

FIGURE 1.—Trends in the lead industry in the United States, 1900-1942. Imports include lead in ore, base bullion, pig lead, and scrap; exports include pigs, bars, and scrap lead exported in manufactures with benefit of draw-back.

concentrates was established for overquota production; this was equivalent to 2.75 cents per pound premium. The premium-price plan was continued without further change throughout 1942. On February 18, 1943, the scope of the Metals Reserve Co. plan was broadened to include an additional premium of 2.75 cents a pound, and the effective time limit was extended to July 31, 1945. Under the revised plan the highest possible payment for excess production amounted to 12 cents a pound, New York basis, depending upon the quotas assigned to the particular mine.

DOMESTIC PRODUCTION

Pig lead is produced at primary plants that treat ore and a small amount of scrap and at secondary plants that treat scrap exclusively. Both types of plants may produce refined lead or antimonial lead. Because of the large quantity of battery scrap treated at secondary

Digitized by Google

smelters, their output is essentially antimonial-lead alloys. Figures for production of refined lead at secondary plants are given in the section on Secondary Lead.

The following table shows production of refined lead and antimonial lead at primary refineries from 1938 through 1942.

Refined lead and antimonial lead produced at primary refineries in the United States, 1938–42, in short tons

Year	Refined lead				Antimonial lead
	From domestic ores and base bullion	From foreign ores and base bullion	From scrap	Total	
1938	331,964	51,705	24,800	408,469	24,123
1939	420,967	63,068	29,011	513,046	21,995
1940	433,065	100,114	16,588	549,767	29,762
1941	470,517	100,450	13,454	584,421	40,237
1942	467,367	99,472	12,856	579,695	51,762

PRIMARY LEAD

Refinery production.—Production of refined primary lead decreased less than 1 percent in 1942.

Refined primary lead produced in the United States, 1938–42, by classes and sources

Year	Production (short tons) by—						Total production [1]		
	Class			Source			Short tons	Value	
	Desilverized lead [1] [2]	Soft lead [2]		From domestic ores and base bullion	From foreign ores	From foreign base bullion		Average sales price per pound	Total calculated value
		Desilverized	Undesilverized						
1938	243,891	31,986	107,792	331,964	32,862	18,843	383,669	$0.046	$35,298,000
1939	280,356	65,349	138,330	420,967	24,652	38,416	484,035	.047	45,499,000
1940	336,456	43,400	153,323	433,065	83,563	16,551	533,179	.050	53,378,000
1941	366,385	39,872	164,710	470,517	74,166	26,284	570,967	.057	65,090,000
1942	343,971	42,094	180,774	467,367	81,485	17,987	566,839	.063	71,422,000

[1] Lead content of antimonial lead excluded.
[2] Desilverized soft lead excluded.
[3] Includes lead derived from Missouri ores and other nonargentiferous ores.

Sources of primary lead.—Of the total refined primary lead produced in 1942, 82 percent was derived from domestic ores and base bullion and 18 percent from foreign, the same ratio as in 1941. Production from foreign ores increased 10 percent to within 2 percent of the record established in 1940, but lead refined from foreign base bullion was 32 percent less. The marked drop in output of lead from Mexican base bullion is due to larger quantities of bullion being refined in Mexico and does not indicate a corresponding decrease in total Mexican output of lead. This loss was offset in part by a marked increase in base bullion from Australia. Details of the sources of lead from domestic ores are given in the section on Mine Production.

Grand total	383,669	484,035	533,179	570,967	566,839

Antimonial lead.—Antimonial or hard lead is an important by-product of the refining of base bullion, but the quantity derived from this source is only a small part of the country's annual production. The greater part is obtained from the smelting of antimonial-lead scrap, and some is produced by mixing metallic antimony with refined soft lead.

Production data from lead-smelting plants that handle scrap materials exclusively are summarized in the following section and discussed in detail in the chapter on Secondary Metals—Nonferrous. A large quantity of hard-lead scrap also is treated at primary smelters and refineries; the production of antimonial lead at such plants is shown in the following table. Since 1939 production has increased steadily, but in general the percentage of antimony contained has declined correspondingly.

Antimonial lead produced at primary lead refineries in the United States, 1938–42

Year	Production (short tons)	Antimony content		Lead content by difference (short tons)			
		Short tons	Percent	From domestic ore	From foreign ore	From scrap	Total
1938	24,123	2,809	11.6	6,759	3,385	11,170	21,314
1939	21,995	2,031	9.2	4,117	3,189	12,658	19,964
1940	29,762	2,944	9.9	7,364	3,023	16,431	26,818
1941	40,237	3,510	8.7	14,852	8,013	13,862	36,727
1942	51,762	3,524	6.8	24,512	12,165	11,561	48,238

SECONDARY LEAD

Although some scrap lead is treated at primary plants, the major portion is refined at a large number of plants that operate exclusively on secondary materials. Secondary lead is recovered in the form of refined lead, antimonial lead, other alloys, and chemicals. Recovery at primary and other plants in 1941 and 1942 is shown in the following table. Secondary lead recovered in 1942 was 19 percent less than in 1941 and was equivalent to 69 percent of the domestic refined primary

Digitized by Google

lead output. Further details appear in the chapter on Secondary Metals—Nonferrous.

Secondary lead recovered in the United States, 1941–42, in short tons

	1941	1942
As refined metal:		
At primary plants	13,454	12,856
At other plants	61,810	55,746
	75,264	68,602
In antimonial lead:		
At primary plants	13,862	11,561
At other plants	192,660	158,998
	206,522	170,559
In other alloys[1]	115,630	83,840
Grand total:		
Short tons	397,416	323,001
Value	$45,305,400	$40,698,100

[1] Includes some lead in chemical compounds.

LEAD PIGMENTS

Lead pigments manufactured in 1942 contained 223,338 tons of lead—an 18-percent decrease from 1941. Of the 206,680 tons of lead in pigments derived from refined pig lead, litharge contained 42 percent, white lead 36 percent, red lead 22 percent, and sublimed lead, leaded zinc oxide, and orange mineral less than 1 percent. Leaded zinc oxide and sublimed lead are the principal pigments of which the lead content is derived from ores. Details of production and consumption of lead pigments are given in the chapter on Lead and Zinc Pigments and Zinc Salts.

Lead in pigments produced in the United States, 1938–42, by sources, in short tons [1]

Year	Lead in pigments from—				Year	Lead in pigments from—			
	Ore		Metal	Total		Ore		Metal	Total
	Domestic	Foreign				Domestic	Foreign		
1938	12,025	----------	163,815	175,840	1941	23,951	290	248,674	[2] 273,315
1939	15,171	----------	200,390	215,561	1942	15,949	707	206,680	[3] 223,338
1940	16,869	----------	196,235	213,104					

[1] Includes also lead recovered in leaded zinc oxide.
[2] Includes 400 tons from scrap.
[3] Includes 2 tons from scrap.

MINE PRODUCTION

Mine production of lead (including that made into lead pigments) in the United States and Alaska increased 8 percent in 1942, the advance being credited to an over-all gain of 4 percent in the Western States and Alaska and 12 percent in the Central States, which more than compensated for a decline of 19 percent in the Eastern States. Production of lead from southeastern Missouri increased 33,090 tons to a total of 197,432 tons, or about 40 percent of the entire United

Digitized by Google

States production. The output from the Tri-State region amounted to 34,341 tons, a drop of 6,739 tons and a reversal of the trend of 1941. A gain in southwestern Missouri was too small to balance losses in the greater productive States of Oklahoma and Kansas. Idaho continued to be the leading producer of the Western States with a 9-percent increase, followed by Utah and Montana with a 3-percent rise and 6-percent loss, respectively. The decrease in Montana's total production of recoverable lead was due largely to the closing in May of nearly all the zinc-lead mines of the Anaconda Copper Mining Co. at Butte in favor of maintaining copper production in the face of labor shortages. Arizona produced 866 tons less than during the record year of 1941, largely because of the decline in output of zinc-lead ore from the Tennessee-Schuylkill mine at Chloride and the suspension in January of the milling of zinc-lead ore from the Hillside mine. In Colorado and Washington the recoverable mine production of lead continued to gain, but the output from Nevada, largely from the Pioche district, and from New Mexico declined. Additional details of production by mines, districts, and States may be found in the State chapters.

Mine production of recoverable lead in the United States, 1925–29 (average) and 1938–42, by States, in short tons

[1] Total for Virginia but almost entirely from Austinville district.

STOCKS

Producers' stocks.—Lead stocks, as reported by the American Bureau of Metal Statistics, are shown in the following table. Stocks of refined and antimonial lead include metal held by all primary refiners and by most refiners of secondary material who produce common soft lead. Foreign lead refined in the United States and entered for domestic consumption is included.

Lead stocks at end of year at smelters and refineries in the United States, 1938–42, in short tons

	1938	1939	1940	1941	1942
Refined pig lead	102,489	52,783	32,458	15,973	28,815
Antimonial lead	13,413	5,994	8,468	4,212	6,122
	115,902	58,777	40,926	20,185	34,937
Lead in base bullion—					
At smelters and refineries	18,693	10,337	9,166	8,594	7,359
In transit to refineries	2,339	3,521	3,457	2,215	1,706
In process at refineries	16,690	15,958	18,141	17,709	13,925
	37,722	29,816	30,764	28,518	22,990
Lead in ore and matte and in process at smelters	56,332	59,486	71,722	51,446	59,247
	209,956	148,079	143,412	100,149	117,174

Digitized by Google

In contrast with 1941 the excess of production over shipments in 1942 resulted in an over-all gain in inventories for the year. Stocks of refined and antimonial lead at refineries, which totaled approximately 20,200 tons at the end of 1941, steadily increased to 31,400 tons by the end of April, followed by a general decline to 25,900 tons by the end of August. During the next 3 months increasing output more than balanced nearly constant shipments, and stocks advanced to 35,600 tons by the end of November—the high point for the year. A slight decrease in output in December coupled with a gain in shipments reduced inventories to about 35,000 tons at the end of 1942, a net gain of 73 percent over the total on hand at the end of 1941. Stocks of lead in ore and matte and in process at smelters, in base bullion at smelters and refineries, and in transit to and in process at refineries were 3 percent higher at the end than at the beginning of 1942.

Consumers' stocks.—The data on consumers' stocks by grades at the beginning and end of 1942 are shown in the following table. These results, as obtained from a consumer survey of 500 respondents, are estimated to represent 85 to 90 percent of the consuming industry on the basis of lead consumed, but the same relative percentage does not necessarily hold as regards inventories. Stocks of all grades of domestic lead decreased slightly, but the decided drop in foreign lead caused an over-all decline of 22 percent by the end of 1942.

Consumers' stocks of refined soft lead at beginning and end of 1942, by grades, in short tons [1]

	Domestic			Foreign (all grades)	Total
	Corroding	Chemical	Common		
Dec. 31, 1941 [2]	29,900	17,456	32,363	21,245	100,964
Dec. 31, 1942	25,532	16,587	31,360	5,587	79,066

[1] Based upon a survey of 500 respondents.
[2] Revised figures.

DOMESTIC CONSUMPTION

New supply.—The calculated supply of refined primary lead available for consumption in 1942 was 12 percent above that for 1941 and 34 percent above the 1925–29 average (690,916 tons). The figures in the following table do not include variations in producers' stocks and do not indicate the true trend in actual consumption. Moreover, the greater part of the large tonnage of imported lead which swelled the supply in 1942 is still held in Government stock piles.

Refined primary pig lead available for consumption in the United States, 1938–42, in short tons

	1938	1939	1940	1941	1942
Supply:					
Imports	1,905	5,388	149,889	274,189	366,497
Production	383,669	484,035	533,179	570,967	566,839
	385,574	489,423	683,068	845,156	933,336
Withdrawn: Exports	[1] 45,866	74,392	[2] 49,079	14,359	[3] 5,814
Supply available for consumption	339,708	415,031	633,989	830,797	927,522

[1] Includes small quantity of "sheets and pipes"; figures not separable.
[2] Includes 25,324 tons of foreign refined lead re-exported, according to American Bureau of Metal Statistics; official figures not available.
[3] Includes 3,874 tons of foreign refined lead re-exported, according to records of the Department of Commerce.

Digitized by Google

Consumption.—Although figures showing the total consumption of lead, primary and secondary (including antimonial lead), are not available for 1942 the total probably was somewhat less than the record 1,050,000 tons consumed in 1941 as reported by the American Bureau of Metal Statistics. Owing to the return of large quantities of secondary lead in discarded and obsolete articles and from the lead-consuming industries, the total consumption of pig lead greatly exceeds the supply of new lead. The supply of new lead was greater in 1942, but the actual tonnage released to consumers was considerably less because of use restrictions, and the proportion of secondary and scrap lead to primary material was probably even higher than normal.

Consumption of refined soft lead in the United States, 1941–42, by grades and uses, in short tons [1]

	1941	1942		1941	1942
By grades:			By uses—Continued.		
Domestic:			Collapsible tubes	3,726	9,966
Corroding	289,679	227,207	Foil	51,516	9,375
Chemical	150,206	142,213	Pipes, traps, and bends	32,946	21,395
Common	257,113	134,101	Sheet lead	35,480	31,774
Foreign: All grades	115,649	92,568	Solder	35,630	34,764
			Storage batteries	73,982	41,135
Total consumed	812,647	596,089	Terneplate	2,069	2,337
			Type metals	2,975	943
By uses:			White lead	83,230	58,372
Ammunition	32,959	48,025	Red lead and litharge	143,496	98,667
Bearing metals	10,160	12,648	Chemicals and insecticides	8,861	6,298
Cable covering	141,161	113,374	Other uses [2]	112,833	94,904
Calking lead	32,380	9,038			
Casting metals	9,243	3,074	Total consumed	812,647	596,089

[1] Based upon survey of 500 respondents; 1941 figures are revised, but 1942 figures are preliminary and subject to revision.
[2] Includes consumption of lead in manufacture of tetraethyl lead, lead used for ships' ballast, annealing, galvanizing, brass and bronze, and other miscellaneous uses.

A consumer survey conducted by the Bureau of Mines for the second consecutive year disclosed that the consumption of refined soft lead at 500 plants decreased 27 percent in 1942. Judging from available data as regards supply, shipments, and producers' stocks, receipts of 607,431 tons of refined soft lead by those consumers canvassed indicate that the 1942 coverage was probably 85 to 90 percent. Antimonial lead, unrefined scrap lead, and lead in alloys are not included. The accompanying table presents a 2-year comparison by grades and by uses of soft lead. Consumption of all three grades of domestically refined lead and foreign lead declined, common lead showing the greatest drop (48 percent). Of the total amount used in 1942 (comparative 1941 percentages in parentheses), corroding accounted for 38 (36) percent, chemical 24 (18) percent, common 23 (32) percent, and all grades of foreign 15 (14) percent. Consumption of lead by uses decreased during 1942 except that consumed in making ammunition, bearing metals, collapsible tubes, and terneplate. Use in solder remained virtually unchanged. Cable covering was the largest of the principal uses of soft lead in 1942, followed in order by red lead, litharge, white lead, ammunition, and storage batteries. The effect of conservation measures, use restrictions, and the general industrial change-over from peacetime to wartime economy is particularly apparent with respect to some of the principal uses of lead. The cessation of automobile manufacturing largely was respon-

Digitized by Google

sible for the drop in the consumption of lead for storage batteries and, to some extent, the decline in lead used for red lead and litharge which also enters into the manufacture of batteries and pigments. White lead, the most widely used lead paint pigment, showed a considerable decline, and foil dropped markedly, largely owing to the restrictions placed on the consumption of lead in making foil for packaging.

PRICES

The two major markets for lead in the United States are New York and St. Louis; much of the lead produced in this country is sold at prices normally based upon quotations in these markets. Since suspension of the London Metal Exchange dealings in September 1939 for the duration of the war the London market has had no actual influence on New York quotations, and the differential between St. Louis and New York prices has remained at 0.15 cent a pound, an amount approximating the freight charges between the two points.

At the beginning of the year prices for pig lead were 5.70 cents at St. Louis and 5.85 cents at New York, both prices having prevailed since March 26, 1941. Effective January 13, 1942, the Office of Price Administration established the ceiling price for lead at 6.35 cents, St. Louis, and 6.50 cents, New York, at which point it remained for the remainder of 1942.

The official London maximum price of £25 per long ton, duty paid, for Empire and foreign lead, as fixed by the British Ministry of Supply in December 1939, remained unchanged during 1942.

Average monthly and yearly quoted prices of lead at St. Louis, New York, and London, 1938–42, in cents per pound [1]

Month	1940			1941			1942

[1] St. Louis: Metal Statistics, 1943, p. 465. New York: Metal Statistics, 1943, p. 457.
[2] London Metal Exchange dealings suspended for duration of war. Official maximum price fixed by British Ministry of Supply at £25 in December 1939.

FOREIGN TRADE [3]

The continued upward trend in imports of lead was most significant in 1942. The total receipts of foreign material, principally as refined metal but also as lead in ore, matte, and base bullion, were sufficient not only to supplement the domestic refinery production but also to allow reserve stock piling of a large tonnage of pig lead. The result

[3] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Digitized by Google

of this increased supply, coupled with Government control, was to place lead in the position of a substitute metal.

Imports.—Total imports of lead in 1942 again broke all records largely on account of a 35-percent increase in receipts of foreign refined lead over 1941. In this category Mexico furnished 52 percent, Australia nearly 23 percent, Canada 19 percent, and Peru 6 percent as compared with 36, 16, 33, and 15 percent, respectively, in 1941. Nearly all imports of base bullion (97 percent) in 1942 came from Australia, which heretofore has furnished little or no material of this class. Since the war, however, lead bullion in excess of that which could be refined in Australia has been shipped to the United States rather than to other metallurgical centers barred by wartime restrictions. Lead in ores and matte came from many countries but principally from Newfoundland, Australia, Peru, and Canada, which together supplied 81 percent of the total imports of this material.

Total lead imported into the United States, 1938–42, by forms in which imported, in short tons [1]

Year	Lead in ore and matte	Lead in base bullion	Pigs, bars, and old	Total lead content
1938	45,370	15,296	3,235	63,901
1939	30,842	48,902	7,139	86,883
1940	111,300	19,624	151,568	282,492

1942	972	274	66,096	245	210	19,631

Exports.—Total exports (excluding re-exports of foreign refined lead) of lead in 1942 were much less than in 1941. The marked drop from the high level of 1939 resulted from the restrictions imposed under the Export Control Act of 1940.

[2] In addition, 25,324 tons of foreign lead were re-exported, according to American Bureau of Metal Statistics; official figures not available.
[3] In addition, 3,874 tons of foreign lead were re-exported, according to records of the Department of Commerce.
[4] Less than 1 ton.

WORLD ASPECTS OF THE LEAD INDUSTRY

Since 1939 the lack of production data from many of the important lead-producing countries has precluded any official statement of world output. According to estimates published by the Metal Bulletin, London, world smelter production of lead in 1941 reached 1,770,000 metric tons, a slight gain over the 1940 estimate of 1,700,000 tons from the same source. Although no figures are available for 1942, it is doubtful if total smelter production has increased appreciably, if at all. The Bureau of Mines estimated that in 1942 the world mine production of lead (recoverable lead content) amounted to roughly 1,635,000 metric tons, an indication that production did not increase. Based on estimates by countries, about 80 percent of the world's supply of lead ore by the end of 1942 was controlled by, or available to, the United Nations.

REVIEW BY COUNTRIES

Argentina.—Production from the lead-zinc properties in the province of Jujuy came principally from the Aguilar mine of the Compania Minera Aguilar S. A., subsidiary of the St. Joseph Lead Co. The output in 1942 was curtailed owing to a shortage of fuel oil. The monthly production rate in January 1943 was estimated at 3,000 metric tons of lead concentrates. Total exports of lead concentrates (containing 74 percent lead, 6 percent zinc, and 50 ounces of silver) during January 1942 aggregated 1,950 metric tons; for the remainder of the year no further shipments were recorded. Stocks at the Aguilar mine and the port of Santa Fé on January 1, 1943, totaled 14,047 metric tons.

Australia.—Mining activities in Australia in 1942 were confronted with many adversities such as higher taxation, drafting of labor into the armed services, and flow of miners into higher paying munitions industries. The Minerals Production Committee was authorized by the Federal Government to expedite the mining and treatment of strategic minerals by furnishing financial aid, providing equipment, and helping to alleviate manpower shortages; it also engaged in mining on its own account.

Production of lead concentrates was maintained at Mount Isa Mines, Ltd. The Zinc Corporation, Ltd., reported lead lode ore reserves of 3,800,000 tons at the beginning of 1942.

Digitized by Google

Bolivia.—Mine production of lead in Bolivia, largely from small mines in the La Quiaca region, decreased from 15,653 metric tons (lead content in ore) in 1941 to 12,360 tons in 1942. All ore and concentrates are exported. No further information has been received regarding the erection of a lead smelter in the province of Sud Chichos. It was reported that such a plant would be built through the use of funds allotted by the Bolivian Banco Minero.

Brazil.—The Furnas mine in the Iporanga district continued to be the principal lead producer in 1942. Four additional deposits on the Iporanga River, operated by another company, are reported to have estimated reserves of 20,000 metric tons of galena. The State of São Paulo is having the mineral resources of this entire zone explored. The small lead smelter at Apiai, São Paulo, produced 10 tons of lead during the year, all of which was consumed in Brazil.

Burma.—The Bawdwin lead-zinc mines of the Burma Corporation were seized by the Japanese near the end of April 1942. Assuming that the Japanese successfully repair the reported damage to mines, mill, and smelter, the potential peacetime annual output of about 80,000 tons of lead would become available to them.

Canada.—Production of lead in Canada increased from 230,084 short tons in 1941 to 255,751 short tons in 1942. These figures include smelter production plus lead contained in exported ore. Well over 95 percent of the lead is mined in British Columbia almost entirely from the Sullivan mine of the Consolidated Mining & Smelting Co. Sales of primary lead in Canada were placed under a system of control in 1942 whereby no producer could sell or supply primary or secondary lead or lead-base alloys in pig or ingot form without written approval of the Metals Controller of Canada; lead-base type metal, babbitt, and solder were excepted. Extensive exploratory drilling for new deposits was done in an effort to replace the heavy drain on existing reserves. Gulf Lead Mines, Ltd., was organized to continue the development of lead-zinc deposits on the east coast of Hudson Bay. Ore supplies are being supplemented by numerous efforts to recover lead from residues. The slag dumps at the gold mines of the Kirkland Lake and Larder Lake areas of Ontario yielded considerable lead, and the Western Exploration mill produced lead concentrates from tailings dredged from Slocan Lake. The New Calumet was expected to have its new 300-ton zinc-lead concentrator in operation before the end of 1942.

Mexico.—Mine production of lead in Mexico increased 27 percent from 155,259 metric tons (lead content of ore) in 1941 to 197,019 tons during 1942. The most important event in 1942 was the Bateman-Juarez-Tellez agreement between the Metals Reserve Co., the State Department, and the Mexican Government, under which the Metals Reserve Co. contracted to buy 250,000 tons of lead at 5.40 cents a pound each year for the duration of the war; the contract could be extended by mutual agreement after the war. Mexico agreed to stabilize taxes on lead, freeze freight rates, and hold in abeyance certain clauses in the labor laws. In spite of the agreement labor difficulties arose, and at the end of the year the miners were threatening to strike for a 25-percent wage increase. On December 23 a reciprocal trade pact with the United States reduced the duty on lead and lead in ore to 50 percent of the amount set by the United States Tariff Act of 1930. It will remain at this level until 30 days after

Digitized by Google

the termination of the national emergency, at which time it will be established at 20 percent below the rate set in the Tariff Act of 1930.

In 1942 the Avalos lead smelter of the American Smelting & Refining Co. at Chihuahua treated 466,549 metric tons of ore containing 118,401 tons of lead, compared with 362,211 tons of ore containing 94,947 tons of lead in 1941. Production from the five principal mines in the Chihuahua district increased in 1942, despite the fact that the Potosí Mining Co. exhausted its main ore body after nearly 100 years of operation. Nearly all the cooperative mining companies reverted to private ownership and operation in 1942. The Eagle Picher Lead Co. and the American Smelting & Refining Co. reopened old lead-zinc mines in the Taxco district. The El Bote mine, owned by the Sociedad Cooperativa Minera "El Bote", S. C. L., produced 30 tons of lead a day (content in concentrates).

Newfoundland.—The mine production of lead in terms of lead content of all concentrates produced amounted to 28,007 short tons in 1942 as compared with 33,166 tons in 1941.

North Africa.—The North African military campaign, starting in November 1942 and successfully concluded by the Allies in May 1943, aroused interest in raw materials thus made available to the United Nations. The largest lead producer in Morocco is the Aouli mine, 15 miles northeast of Midelt. Reserves at this property have been estimated at 60,000 tons on the basis of 75 percent lead concentrates. The concentrating plant has a capacity of 20 tons an hour.

The lead-mining industry in Tunisia is active; production comes from scattered deposits in the northern half of the country from ore (concentrates?) reportedly averaging 60 to 70 percent lead. In normal times about 90 percent of the Tunisian lead ores are treated at the smelter owned by the Peñarroya Co. at Mégrine, near Tunis, which has a capacity of about 25,000 metric tons of lead annually. On May 1, 1942, 3,700 tons of lead were in stock at the smelter. For the period January 1 to May 1, 1942, production of lead concentrates in Morocco, Algeria, and Tunisia totaled 7,839 tons.

Peru.—The lead content of concentrates produced in Peru during 1942 was estimated to be about 55,830 metric tons, compared with 54,822 tons in 1941. This estimate is based upon the reports of companies producing 80 percent of the total lead output of Peru. Exports for 1942 included 3,117 metric tons of ore, 7,616 tons of concentrates, and 36,979 metric tons of refined lead compared with an estimated 8,000, 12,000, and 38,000 tons, respectively, in 1941. The largest lead producer is the Huaron mine; reserves are estimated to be 180,000 tons of positive ore and 500,000 tons of probable ore averaging 6.89 percent lead, 8.73 percent zinc, and 319 grams of silver per ton. The Oroya lead smelter, with a capacity to produce 4,000 tons of refined lead a month, recovered 42,246 metric tons of lead in 1942 (34,375 tons in 1941).

Spain.—According to the official figures of the General Mining Board of Spain, the 1942 output was 51,118 metric tons of lead concentrates compared with 43,728 tons in 1941. The most important deposits are in the Sierra Morena and the southeastern coast section. There are five lead smelters that reportedly can produce 32,000 to 35,000 tons of lead annually. Domestic consumption is about 23,000 tons, leaving a surplus of about 12,000 tons available for export.

Sweden.—The suspension of virtually all imports of lead in addi-

Digitized by Google

tion to other metals into Sweden due to the conditions of war has forced the Boliden Mining Co. to further intensify its efforts to produce the metal from Swedish deposits. Reportedly by the summer of 1943, the company will start commercial-scale production from the mine at Laisvall. Lead concentrates produced at this property have a lead content of 80 percent and are shipped to the Rönnskär smelter at Skelleftead.

GENERAL SUMMARY

In 1942, a year of broken records resulting from the "all-out" industrial mobilization of a nation at war, the zinc industry was outstanding in its ability to more than maintain the delicate balance between supply and demand. With the assistance of increasing Government regulatory measures, an expanded smelting industry increased its output 7 percent above the 1941 record to establish once more an all-time high level of production and to show a marked gain in stocks. Conservation measures restricting the use of zinc to essential needs resulted in an over-all 12-percent drop in domestic consumption, but consumers' stocks advanced 6 percent. The general decrease in domestic shipments of zinc by smelters was largely balanced by a gain in exports, principally for Lend-Lease accounts. The particular emphasis placed on the use of High-Grade zinc resulted in a 27-percent rise in production of high-purity metal, of which increasing amounts were made by redistillation of the lower grades of zinc. Partly as a result of this and also because of use restrictions, the lower grades of zinc decreased 8 percent. At the close of 1942, smelters were operating at usable capacity, with additional facilities under construction expected to bring an already enlarged output to a peak by the middle of 1943.

Domestic mine output showed only a slight gain in 1942 despite the incentive of premium prices, and to fulfill requirements and operate at capacity smelters continued to use foreign ore in greater amounts than ever before. Total imports in 1942 exceeded all previous records, as did domestic output of zinc from foreign ores, which amounted to 29 percent of the total production.

The established ceiling price of 8.25 cents a pound at St. Louis for Prime Western zinc was unchanged during 1942 and compares with the average of 7.48 cents in 1941 and 6.34 cents in 1940.

[1] This report deals primarily with the smelting branch of the industry. Full details of zinc mining are given in the various State reports. Some zinc ore is used directly in the manufacture of zinc pigments. (See chapter on Lead and Zinc Pigments and Zinc Salts.)

WAR-AGENCY REGULATIONS

Despite the excellent cooperation between the zinc industry and the Government during 1940 and 1941, the increasingly critical status of the over-all zinc supply problem necessitated more definite control measures. Under General Preference Order M–11, in effect at the beginning of 1942, the War Production Board controlled the supply of slab zinc. However, this right was exercised over only a part of the total zinc output, as the percentage requirements for the "pool" increased from 31 in January to 75 of High Grade and 50 of lower grades in May, the balance of output being distributed by the industry. On May 1 Order M–11 was amended placing slab zinc under complete allocation effective June 1. A subsequent amendment on February 9, 1943, tightened the control on zinc by placing remelt zinc as well as refined metal under allocation. Because of the shortage of zinc dust for war purposes that developed at the end of 1942, this material, under the "pool" arrangement since June 1, was placed under complete allocation on December 22, 1942, according to General Preference Order M–11–1. Conservation Order M–11–b, issued July 24, restricted the use of zinc in a large number of manufactured products and prohibited others, the exceptions being principally for United States Government and Lend-Lease accounts. An amendment to this order prohibited the use of zinc after October 10 for making closures for glass containers, one of the largest peacetime uses of rolled zinc. A later amendment dated November 26 added to the list of prohibited items. Other restrictions were subsequently imposed by General Limitation Order L–71 as amended October 2, 1942, and amendment 1 to General Conservation Order M–99, which referred to production of dry-cell batteries and engravers' plates, respectively.

In an effort to increase domestic mine production, the Office of Production Management, jointly with the Office of Price Adminis-

Digitized by Google

tration, on January 13, 1942, announced the details of a premium-price plan whereby producers (miners) of zinc (copper and lead were also included in the plan) received, through the Metals Reserve Co., 11 cents a pound for zinc produced in excess of quotas based upon 1941 output as against the regular established ceiling price of 8.25 cents at East St. Louis. This plan became effective February 1, 1942, for 2¼ years. In the Tri-State district the miner was paid an extra $28.05 a ton for 60-percent concentrates, this being declared the equivalent of the 2.75 cents a pound premium. Later in the year the figure was adjusted to $29.70. This plan was continued without further change in 1942, and although the expected increase in the rate of production did not materialize, the maintenance of past production was in itself an accomplishment. On February 18, 1943, Jesse Jones, Secretary of Commerce, announced that the scope of the Metals Reserve Co. premium-price plan had been broadened to include additional premiums and that the effective time limit had been extended to July 31, 1945. Under the revised plan two additional premiums for zinc were added, bringing the highest possible payment for excess production to a total of 16.50 cents a pound, East St. Louis basis, depending on the quotas assigned to the particular zinc mine.

Figure 1 shows trends in the zinc industry since 1900.

SMELTING CAPACITY

Under the pressure of war requirements a record output of 945,067 short tons of slab zinc was produced from ore and secondary materials in 1942. This total is somewhat short of early estimates largely owing to delays in completing construction of additional smelting capacity caused by priority and manpower problems. The peak production scheduled for the latter part of 1942 will not be reached until well into 1943. By use of this additional capacity under construction it has been estimated that the 1943 production will reach 1,036,000 tons.[2]

An important development regarding zinc production in 1942 was the expansion of facilities for redistillation of the lower grades of zinc into High-Grade metal to supplement the already expanded existing plants that produce High-Grade zinc. This type of operation is already being increased for 1943.

In all probability the scheduled total zinc productive capacity has reached the peak beyond which it will be impractical to go, the principal limiting factor being available supplies of zinc concentrates.

SUPPLY OF ZINC CONCENTRATES

In 1942 the domestic mine production of recoverable zinc increased 2.5 percent over 1941—a notable achievement in view of the decline in quality of ore available for mining. Premium prices for overquota production stimulated the mining of high-cost ores, and although definite figures are not available it is safe to say that, to effect the small gain in output of recoverable zinc in 1942, a much larger gross weight of ore had to be mined than in 1941 because of the lower zinc content of the material milled.

In addition to production from mined ore, zinc was recovered from ever-increasing amounts of old tailings. The remilling of this low-grade material, in many instances for the second and third time, was

[2] As reported by American Zinc Institute, upon the basis of estimates by producer members that together represent approximately 98 percent of total United States production, including primary and secondary.

Digitized by Google

made possible by advances in milling technology plus the allowed premium payments for the zinc produced. Plants at Helena, Mont., and Tooele, Utah, added to the over-all supply in 1942 by treating lead blast-furnace slag for the recovery of zinc, and a third plant of this type, under construction in Idaho at the end of 1942, will be ready for operation in 1943.

An indicated decrease in production from domestic sources, to a large extent determined by a declining output from the Central States,

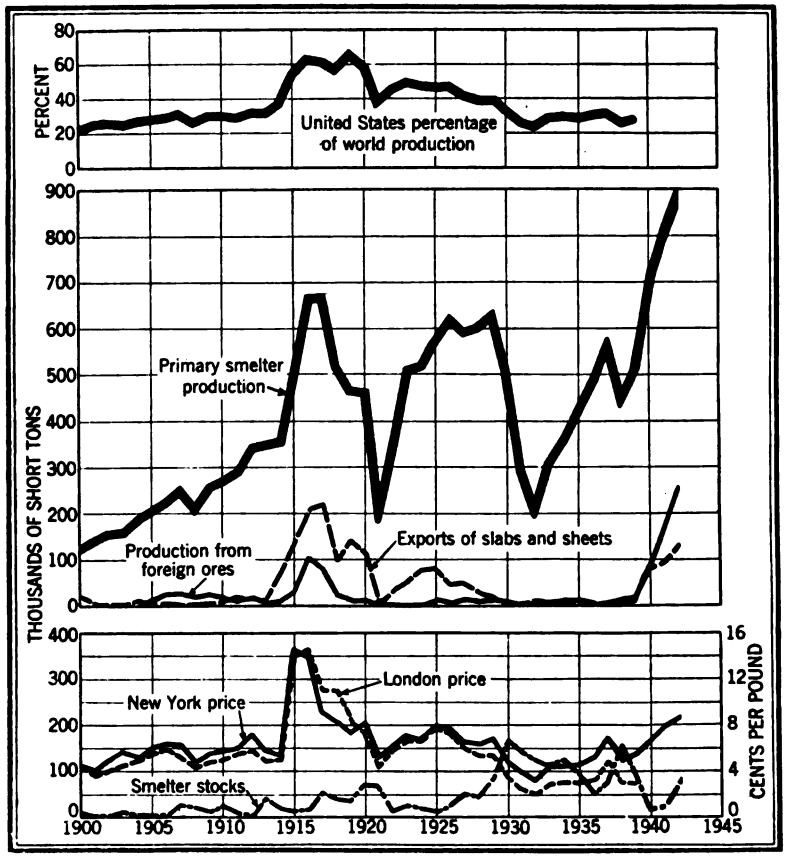

FIGURE 1.—Trends in the zinc industry in the United States, 1900–1942. Imports for consumption of slab and sheet zinc are not shown. Before 1936 they seldom exceeded 500 tons annually, but in recent years they have increased, amounting to 7,456 tons in 1938, 31,138 tons in 1939, 10,164 tons in 1940, 40,559 tons in 1941, and 36,445 tons in 1942.

makes the dependency on imports of foreign ores and concentrates greater than ever before. To keep smelters operating at their expanded capacity in 1942, it was necessary to import foreign material totaling an amount equal to 10 times that in 1939, and estimates of increasing imports for 1943 and 1944 indicate that zinc produced from foreign raw material will exceed the total metal output from domestic mines. The foreign supply, principally from the Western Hemisphere, comes largely from Mexico and Canada. Imports from these two countries, which supplied nearly two-thirds of the minimum import requirements in 1942, fortunately move by all-rail routes to

Digitized by Google

the United States and may be counted on for future supplies, with nearly equal assurance as domestic production.

The United States has encouraged further development of foreign ore deposits by lending both technical and financial assistance to many mines in other countries through the auspices of the Board of Economic Warfare and the Metals Reserve Co. Definite contracts made by the latter agency for production and delivery of specific amounts have already resulted in gains in foreign output; assuming that necessary increases in water-borne imports can be relied upon, the minimum requirements for 1943 are assured.

DOMESTIC PRODUCTION

PRODUCTION OF PRIMARY AND REDISTILLED SECONDARY SLAB ZINC

The production of 891,872 short tons of primary slab zinc from domestic and foreign ores in 1942 was the highest ever made and exceeded the previous record of 1941 by 8 percent. This increase was made possible by a 55-percent larger output from foreign ore, which more than balanced the 3-percent decline in production from domestic ore.

Heavy demands on a dwindling supply of zinc scrap reduced the output of redistilled slab zinc in 1942 by 11 percent. To prevent inadvertent duplication, figures for the output of remelted secondary slab zinc are not included with those for redistilled metal. In 1942, 8,637 tons were recovered by remelting purchased scrap. Zinc rolling mills and other consumers recover considerably more than this from their own plant scrap, but such metal normally does not enter the market as scrap and is therefore not measured statistically.

Primary and redistilled secondary slab zinc produced in the United States, 1938–42, in short tons

Year	Primary			Redistilled secondary	Total (excludes zinc recovered by remelting)
	Domestic	Foreign [1]	Total		
1938	436,007	10,334	446,341	31,613	477,954
1939	491,058	16,178	507,236	50,428	557,664
1940	589,988	85,287	675,275	48,917	724,192
1941	652,599	169,421	822,020	59,503	881,523
1942	629,957	261,915	891,872	53,195	945,067

[1] Most of the foreign ores smelted in the United States in 1938 originated in Peru; in 1939, in Mexico, Peru, and Argentina; in 1940–41, principally in Mexico, Canada, Newfoundland, and Peru; and in 1942, in Mexico, Canada, Argentina, Newfoundland, Australia, and Peru.

DISTILLED AND ELECTROLYTIC ZINC

Of the primary zinc produced in 1942, 72 percent was distilled and 28 percent electrolytic compared with 73 and 27 percent in 1941.

The tremendous increase in the demand for wrought-brass products for military uses emphasized more than ever the importance of High-Grade slab zinc. In fact, it was found necessary to greatly enlarge the existing capacity to produce High-Grade zinc by redistilling Selected and Prime Western grades, the supply of which was not so critical. As a result the production of Special High Grade gained 14 percent and Regular High Grade 41 percent in contrast with Prime Western production, which was 21 percent lower. To avoid duplication the lower grades of zinc consumed in this operation

Digitized by Google

do not appear in the production figures shown in the following table, but the High-Grade slab zinc produced is included. Of the total 1942 production, 29 percent was Prime Western, 27 percent Regular High Grade, 24 percent Special High Grade, 9 percent Brass Special, 8 percent Intermediate, and 3 percent Selected.

Distilled and electrolytic zinc, primary and secondary, produced in the United States, 1938–42, in short tons

APPORTIONED ACCORDING TO METHOD OF REDUCTION

Year	Electrolytic primary	Distilled primary	Redistilled secondary [1]		Total
			At primary smelters	At secondary smelters	
1938	93,272	353,069	14,003	17,610	477,954

[1] For total production of secondary zinc see chapter on Secondary Metals—Nonferrous.

PRODUCTION OF PRIMARY SLAB ZINC BY STATES

Pennsylvania continued to be the leading producer of primary slab zinc in the United States—a distinction held without interruption since 1934. Montana ranked next followed closely by Illinois. Of the States for which production figures may be released, Oklahoma, Arkansas, and Idaho occupied the next three positions in order of decreasing importance. Arkansas and Oklahoma had less production than in 1941. Illinois was conspicuous with a 44-percent increase in 1942 output. Montana and Idaho, as usual, produced electrolytic zinc only. Illinois and Texas made both electrolytic and distilled metal, and all other producing States confined their operations to distillation alone.

Primary slab zinc produced in the United States, by States where smelted, 1938–42, in short tons

Year	Arkansas	Idaho	Illinois	Montana	Oklahoma	Pennsylvania	Other States [1]	Total	
								Short tons	Value

SECONDARY ZINC

In addition to the redistilled secondary slab zinc (unalloyed) already reported herein, some remelted slab zinc is produced, and a large quantity of secondary zinc is recovered each year in the form of alloys, zinc dust, zinc pigments, and zinc salts. Additional information on secondary zinc is given in the chapter on Secondary Metals—Nonferrous.

BYPRODUCT SULFURIC ACID

Sulfuric acid made from the sulfur dioxide gases produced in roasting zinc blende (sphalerite) is an important byproduct of zinc smelting. To utilize a larger proportion of their acid-producing capacity, some plants also consume large quantities of sulfur. The production of sulfuric acid at zinc-blende roasting plants increased 3 percent during 1942.

Sulfuric acid (60° B. basis) made at zinc-blende roasting plants in the United States, 1938–42

Year	Made from zinc blende [1]		Made from sulfur		Total [1]		
						Value [2]

[1] Includes acid from foreign blende.

[2] At average of sales of 60° acid.

ZINC DUST

Production of zinc dust in 1942 was 7 percent below the record output in 1941. The zinc content of the dust ranged from 95 to 99.5 percent and averaged 97.2 percent. Of the total zinc dust shipped in 1942, 11 percent went to foreign countries. This percentage, based on data submitted to the Bureau of Mines, is probably low because sales to the Treasury Department are listed as domestic shipments, although the material eventually was shipped abroad to our Allies. Government restrictions curbing gold and silver mining resulted in a sharp decline in the use of zinc dust for precipitating these metals. Direct war uses, such as the use of dust in smoke screens and chemical-warfare reagents, continued to increase. The largest single use for zinc dust was in the production of sodium hydrosulfite. Production and shipments during 1942 about balanced, so stocks at the end of the year were approximately the same as at the beginning. The average price of zinc dust shipped to domestic consumers in 1942 was 10.4 cents per pound as compared with an average of 9.3 cents in 1941. The raw materials used to manufacture dust are reviewed in the chapter on Secondary Metals—Nonferrous, since approximately 80 percent of it is produced from scrap items, principally galvanizers' dross. The balance is made from zinc ore, slab zinc, and as a byproduct of zinc refining.

1939	16,835	2,367,861	.070	1942	22,805	4,789,050	.105
1940	20,731	3,404,970	.082				

[1] All produced by distillation.

ZINC PIGMENTS AND SALTS

The principal zinc pigments are zinc oxide and lithopone, and the principal salts are the chloride and sulfate. These products are manufactured from various zinciferous materials including ore, metal, scrap, and residues. Details of the production of zinc pigments and salts are given in the chapter on Lead and Zinc Pigments and Zinc Salts.

MINE PRODUCTION

Mine production of zinc in the United States increased only 2.5 percent during 1942 to a total of 768,025 short tons of recoverable zinc. The Western States advanced 28,226 tons or 10 percent, the Central States declined 17,825 tons or 6 percent, and the Eastern States increased 8,499 tons or 4 percent. Oklahoma continued to be the principal producer in the country by a wide margin, contributing more than half of the yield from the Central States, which supplied 34 percent of the total mine production in 1942. The rapid depletion of ore reserves in the Central States lowered production in all but Wisconsin, Illinois, and Missouri. The Tri-State (Joplin) region supplied 31 percent of the total domestic production compared with 35 percent in 1941.

All Western States except Montana and Nevada gained in production during 1942 and together contributed 40 percent of the domestic total. Idaho continued to be the largest producer in this region, with a 10-percent increase over the previous record level of 1941. In spite of a drop in production, Montana ranked second, followed closely by New Mexico and Utah. The output of Colorado was more than double that of 1941. The 8-percent gain in Utah's output was due almost entirely to the additional production of the Tooele slag-fuming plant.

Among the Eastern States, New Jersey continued to be the leading producer and maintained its rank as second in importance in the country by mining 94,040 tons of recoverable zinc. The output from New York and Tennessee continued to be higher than in the past. Virginia mine production was somewhat smaller than in 1941.

Additional data on mine production of zinc are given in the separate chapters covering each State.

STOCKS

PRODUCERS' STOCKS

Inventories at primary reduction plants at the end of 1942 were more than triple the amount on hand at the beginning, and the 241-percent increase raised the total to the highest point since 1939. Stocks held at secondary distilling plants, although comparatively small, advanced similarly from 890 to 1,790 tons to bring the over-all gain to 236 percent above 1941. Of the total stocks on hand at the end of the year, 18,058 tons were High Grade and Intermediate, and the remaining 66,364 tons were the lower grades, compared with 18,491 tons and 6,611 tons, respectively, at the end of 1941. Nearly the entire inventory gain can be accounted for by the accumulation of Prime Western grade.

This steadily increasing stock pile has been the outgrowth of the program of conservation, particularly with regard to nonessential uses, coupled with the necessity of building up reserves to a safe working level. Nearly half of the total stock on hand at the end of the year was credited to the account of the Metals Reserve Company. Although subject to allocation, a large proportion of the balance of Prime Western grade zinc probably will be refined into the higher-grade metal at some future date to help fulfill the demand for this critical material.

According to the American Zinc Institute, stocks of slab zinc followed a general downward trend until the end of May and then advanced rapidly during the remaining months of the year.

Stocks of zinc on hand at zinc-reduction plants in the United States at end of year, 1938–42, in short tons

	1938	1939	1940	1941	1942
At primary reduction plants	157,511	83,728	19,212	24,212	82,632
At secondary distilling plants	1,915	2,555	761	890	1,790
	159,426	86,283	19,973	25,102	84,422

Stocks of zinc ore (60 percent concentrates) in the Tri-State district (as reported by the Tri-State Zinc and Lead Ore Producers' Association) on January 3, 1942, were only 1,500 tons but quickly attained the level of 4,970 tons by January 24. Production continued to exceed shipments until the middle of February, when stocks were 5,805 tons. This rise was followed by a slow drop to 3,331 tons on hand at the end of the first quarter. The premium-price plan covering overquota mine production subsequently disturbed normal stock trends by encouraging the practice of making heavy shipments at the end of the month, with a resultant sharp drop in stocks. Throughout April, May, June, and July inventories remained fairly steady near 3,800 tons. August saw an accumulation up to 4,600 tons, but during September, October, and November stocks returned to the general level of 3,800 tons. By the middle of December the total reached 5,116 tons,but heavy shipments resulted in a January 2 inventory of only 957 tons.

According to an American Zinc Institute survey, stocks of ore and concentrates at primary zinc reduction plants on December 31, 1942,

Digitized by Google

totaled 540,339 tons averaging 55 percent zinc compared with 413,427 tons containing 55 percent zinc at the end of 1941. Smaller stocks of ore were also held at plants producing zinc oxide and zinc dust.

Data on stocks of metallic zinc outside the United States continue to be unavailable, owing to the disruption of international trade in zinc ore and strict censorship imposed by the Nations at war.

CONSUMERS' STOCKS

Consumers of slab zinc improved their inventory position in 1942, total stocks on December 31 being 6 percent above the amount on hand on the corresponding date at the end of 1941. Stocks increased steadily from the beginning of the year until August 31, when the maximum of 84,900 tons was attained. This was followed by a drop to 64,800 tons on November 30, the low point for the year. Galvanizers decreased their inventories by 23 percent during the year, but stocks at brass mills rose 57 percent. Because of variance in coverage and certain changes in industrial classification all stock figures for December 31, 1941, which appeared in the 1941 chapter were revised. At the average monthly rate of consumption in 1942 stocks on hand at the end of 1942 were sufficient to supply consumers' requirements for slightly more than 1 month.

In addition to physical stocks on hand at consumers' plants at the end of 1942, a total of nearly 21,000 tons of zinc was in transit to consumers, held for redistillation, and in dealers' hands. Exclusive of an indeterminate amount in bonded warehouses the approximate total slab zinc in stock (including inventories at producers' plants) on December 31, 1942, amounted to 176,000 tons. The comparative figure at the end of 1941 was 106,000 tons.

Consumers' stocks of slab zinc at plants at the beginning and end of 1942, by industries, in short tons

	Galvanizers	Die casters [1]	Brass mills [2]	Zinc rolling mills	Oxide plants	Others	Total
Dec. 31, 1941 [3]	33,437	8,295	20,225	3,373	317	1,207	66,854
Dec. 31, 1942	25,729	9,086	31,713	3,063	532	1,074	71,197

[1] Includes producers of zinc-base die castings, zinc-alloy dies, and zinc-alloy rods.
[2] Includes brass mills, brass ingot makers, and brass foundries.
[3] Revised figures.

DOMESTIC CONSUMPTION

NEW SUPPLY

The following table shows the 5-year trend of primary slab zinc available for consumption in the United States. This calculated quantity, in effect, is equivalent to the slab zinc apparently made available each year for shipment to domestic consumers during the year.

In addition to primary zinc, 52,295 tons of redistilled secondary metal were made available to consumers in 1942 after allowance for increased stocks at secondary smelters.

Available for consumption	375,004	607,464	677,168	762,265	735,865

[1] General imports.
[2] Not separately recorded; estimated.

CONSUMPTION

Approximately 600 companies, representing better than 95 percent of the consuming industry in the United States, used 728,169 tons of slab zinc in 1942—a 12-percent drop from the 1941 total of 827,435 tons. Receipts reported for this same period were 732,512 tons. The apparent discrepancy between this figure and the calculated 788,160 tons of primary and secondary slab zinc apparently shipped to domestic consumers in 1942 may be attributed largely to variances in metal in transit, unaccounted-for metal stored in bonded warehouses, and incomplete coverage of the survey.

Industrial mobilization for total war made startling changes in 1942 in the various phases of the zinc-consuming industry under close Government control. In comparison with 1941, zinc consumed in galvanizing dropped 29 percent and in brass products gained 40 percent. The manufacture of zinc-base alloy was cut more than half, as was the use of slab zinc in zinc oxide, and rolled zinc decreased 8 percent. Details are shown in the following table.

Consumption of slab zinc in the United States, 1941–42, by industries, in short tons [1]

	1941	1942		1941	1942
Galvanizing: [2]			Zinc oxide	16,128	7,977
Sheets	129,028	76,106			
Tubes and pipe	69,749	47,085	Zinc-base alloy:		
Wire	41,408	35,216	Die castings	(3)	58,918
Wire cloth	11,307	7,320	Alloy dies and rod	(3)	21,227
Shapes [4]	99,362	81,764		150,853	80,145
	350,854	247,491	Other uses:		
Brass products:			Slush castings	751	552
Sheets, tubes, etc	195,714	292,820	Wet batteries	1,707	1,667
Ingots, castings, etc	32,324	27,126	Desilverizing lead	1,431	1,251
	228,038	319,946	Miscellaneous [5]	5,564	3,095
				9,513	6,565
Rolled zinc	72,049	66,045	Total: All uses	827,435	728,169

[1] Based upon canvass of approximately 600 companies.
[2] Includes zinc used in electrogalvanizing but excludes sherardizing.
[3] Separate figures for 1941 not available.
[4] Includes pole-line hardware, hollow ware, chains, and miscellaneous articles not elsewhere mentioned.
[5] Includes zinc used in manufacture of zinc dust, bronze powder, alloys, chemicals, castings, and miscellaneous uses not elsewhere mentioned.

Digitized by Google

The consumption of zinc in sheet galvanizing fell off 41 percent, and the amount used for this purpose was 31 percent of the total consumed in all galvanizing compared with 37 percent in 1941. In contrast, zinc used in coating shapes (largely items for military and naval use), although 18 percent under the 1941 figure, comprised 33 percent of the total as against 28 percent in the previous year. The balance of the zinc used in galvanizing went into tubes and pipe, wire, and wire cloth, all totals being less than in 1941.

Of the total slab zinc consumed in 1942, brass mills, foundries, and ingot makers absorbed 44 percent compared with 28 percent in 1941. The marked gain in zinc used for sheets and tubes, amounting to 50 percent, shows the urgent need for brass in cartridges and shell cases. The successful use of steel for certain of these items did not lessen the need for brass; rather it augmented a supply that otherwise would have been limited by the availability of zinc and copper.

The vastly increased use of High-Grade slab zinc by the brass mills left a much smaller proportion available to the producers of zinc-base alloys. Moreover, rigid military specifications prohibited the use of zinc-base die castings in much of the war equipment. As a direct result of the aircraft expansion program, greater quantities of zinc-base alloys were needed for making stamping and forming dies used in fabricating certain airplane parts. Despite the marked gain of this specific type of use, over-all consumption of slab zinc in zinc-base alloy decreased 47 percent.

Zinc rolling mills showed only an 8-percent drop in slab-zinc consumption. In addition to slab zinc, the rolling mills remelt and reroll the metallic scrap originating during their fabricating operations. The scrap thus treated in 1942 amounted to 15,641 tons—a 7-percent gain over 1941. In addition, 2,023 tons of purchased zinc scrap in the form of zinc clippings, old zinc scrap, and engravers' plates were melted and rolled in 1942. No comparative data for 1941 are available. The zinc lost in such waste products as skimmings and ashes totaled 1,639 tons in 1942, an amount equivalent to about 2.4 percent of the net production of rolled zinc.

Production of rolled zinc from these raw materials amounted to 66,439 tons—a 6-percent decrease from 1941. The average value advanced 6 percent from $0.115 in 1941 to $0.122 in 1942. Inventories of rolled zinc were 1,619 tons on December 31, 1942, as compared with 1,300 tons for the same date in 1941—an increase of 25 percent. In addition to actual shipments of rolled zinc in 1942 amounting to 43,647 tons, the rolling mills consumed 38,104 tons of rolled zinc in the manufacture of 22,463 tons of fabricated products, such as battery cans.

Value of slab zinc (all grades)			.075			.087
Value added by rolling			[3] .040			.035

[1] Figures represent net production. In addition, 14,586 tons of strip and ribbon zinc in 1941 and 15,641 tons in 1942 were rerolled from scrap originating in fabricating plants operated in connection with zinc rolling mills.

[2] Data on foil, rod, and wire shown for the first time. Statistics for prior years excluded to prevent revealing individual company figures.

[3] Total figures for 1941 are higher than previously published owing to the addition of foil, rod, and wire.

[4] Allowances made for change in producers' stocks of rolled zinc; stock data obtained for first time in 1942.

The use of slab zinc for zinc oxide was cut to practically half that of 1941. Slab zinc is used to make French process oxide which represented approximately 16 percent of the total oxide made in 1942. Of the total French process oxide produced, about 58 percent was made from slab zinc and the remainder from scrap.

Zinc slab differs from most metals in that it is refined into six grades of purity, ranging from Special High Grade containing 99.99 percent zinc to Prime Western grades containing less than 98.75 percent zinc. The following table shows the grades of zinc consumed by the various industries in 1942. Of the 700,731 tons of domestic slab zinc consumed, 33 percent was Prime Western, 28 percent Special High Grade, and 25 percent Regular High Grade. Nearly 83 percent of the total slab zinc used by galvanizers was Prime Western Grade in 1942; the high grades of zinc, principally in the form of anodes, were used for the most part by the electrogalvanizers. As die castings require the highest-purity metal, consumption by their producers is limited almost entirely to High-Grade slab zinc. War demands for lead-free wrought brass products, such as cartridge cases, were responsible for 84 percent of the slab zinc used by the brass-mill group being of the three highest grades. Zinc rolling mills consume very little slab zinc below the grade of Brass Special.

PRICES

The informal base price ceiling of 8.25 cents a pound for Prime Western at St. Louis, established by the Office of Price Administration on October 9, 1941, was replaced by Price Schedule 81, effective January 29, 1942. As a result, control became stricter, but the quotations remained unchanged. The following formal ceilings were established per pound f. o. b. East St. Louis: Prime Western grade, 8.25 cents; Selected, 8.35 cents; Brass Special, 8.50 cents; and Intermediate, 8.75 cents. Regular High-Grade and Special High-Grade price ceilings were set at 9.25 cents delivered. The base price of 60-percent zinc concentrates in the Joplin region remained stationary at $55.28 per ton. In comparison with 1942 prices, which remained unchanged throughout the year, the average price for Prime Western zinc in 1941 was 7.48 cents a pound and 60-percent concentrates at Joplin, $49.80 a ton. The premium price plan is briefly outlined in this chapter under the heading, War-Agency Regulations.

The official British price of £25 15s. for foreign zinc delivered consumers, duty paid, and £26 10s. for domestic metal remained unchanged throughout 1942.

New York)—1938, 5.74 cents; 1939, 6.16 cents; 1940, 7.38 cents; 1941, 8.48 cents; 1942, 9.25 cents. Brass Special (f. o. b. East St. Louis)—1938, 4.71 cents; 1939, 5.22 cents; 1940, 6.44 cents; 1941, 7.68 cents; 1942, 8.50 cents.
[2] Does not include overquota premium payments made by Metals Reserve Co.

ZINC-REDUCTION PLANTS

ZINC SMELTERS

No change took place during 1942 in the number of zinc smelters. As in 1941, there were 17 active plants, of which 13 continued to operate with horizontal retorts exclusively, one with both horizontal and vertical retorts, two with large vertical retorts, and one with electrothermic furnaces. The total number of retorts reported at the horizontal-retort primary plants was 67,816, 2 percent less than the 69,552 (revised figure) at these plants on December 31, 1941. Of the total retorts reported, 65,508 were in use at the end of 1942—a minor decrease from the 65,969 in operation at the close of 1941. The increased output in 1942 from a numerically smaller number of retorts was accomplished by the use of larger retorts and increased efficiency of operation. Although only 97 percent of the available retorts was in operation at the end of the year, smelting operations

Digitized by Google

were at usable capacity throughout 1942; the remainder, for the most part, comprised a decreasing amount of obsolete equipment that has been idle for some time and is being replaced or reconditioned, and a certain percentage that must necessarily be closed down for repairs and replacement. At the end of 1942, 4,896 new retorts were under construction. Of the 66 vertical retorts in this country, 63 were in operation at the year's end.

Twelve of the primary smelters mix scrap and residues such as skimmings and dross with the ore before distillation. Small quantities of clean metallic scrap are occasionally added to the (condensed or molten) primary zinc without affecting the quality. Supplementing these 17 primary producers, 15 plants made redistilled secondary slab zinc by treating scrap in 2,560 clay retorts, 112 graphite crucibles, and a few special furnaces. One plant at Philadelphia plans to add 3 graphite crucibles in 1943. A part of this available production capacity at secondary smelters is used to produce zinc dust and zinc oxide in addition to slab zinc.

ELECTROLYTIC PLANTS

Five electrolytic plants were in operation by the end of 1942 compared with four in 1941. The American Smelting & Refining Co. started producing slab zinc in its new plant at Corpus Christi, Tex., during October and by December was operating at about 94 percent of capacity. Lack of raw materials delayed completion of additional new cells at the East St. Louis electrolytic refinery. By the end of 1942, 2,814 cells out of a total of 3,038 were in use compared with 2,502 out of 2,526 cells in 1941. The seemingly large number of unused cells is probably due to the fact that some were not completed. At the end of 1942, 156 cells were under construction in the country.

FOREIGN TRADE[3]

IMPORTS

The following tables give total zinc imports (general) in ore and blocks, pigs, or slabs into the United States, 1940–42, and imports for consumption. Of the 368,355 tons of zinc imported in ore, 44 percent came from Mexico, 21 percent from Canada, and 9 percent from Australia. Receipts from Canada were 58 percent higher and from Australia almost four times larger than in 1941. Imports from Belgian Congo dropped considerably, but all other countries supplied more ore than in 1941. Imports of slab zinc from Mexico increased 33 percent, whereas receipts of slab zinc from Canada declined 67 percent.

[3] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

[1] Includes dross and skimmings as follows—1939: 30 tons, valued at $1,918; 1940: 356 tons, $21,815; 1941: 353 tons, $23,028; and 1942: 3,199 tons, $148,272. None reported in 1938.

[2] In addition, manufactures of zinc imported as follows—1938: $463; 1939: $1,545; 1940: $32; 1941: $1,099; 1942: $16.

EXPORTS

The value of exports of zinc ore and manufactured articles containing zinc of foreign and domestic origin (excluding galvanized products, alloys, and pigments) amounted to $24,551,255 in 1942 compared with $14,717,513 in 1941. Slabs, plates, or blocks continued to be the largest export group, and the total shipped to foreign countries increased 50 percent—from 89,309 tons in 1941 to 133,981 tons in 1942. In addition to the items shown in the accompanying tables, considerable zinc is exported each year in brass, pigments, chemicals, and galvanized iron and steel. Export data on zinc pigments and chemicals are given in this volume in the chapter on Lead and Zinc Pigments and Zinc Salts. Much of the zinc used in the manufacture of such products is of foreign origin, and when they are exported a draw-back of 99 percent of the import duty is paid on the basis of zinc contained in the finished product. For 1942, draw-back was paid on 23,047 tons of zinc, of which 8,677 tons had been imported as slabs and 13,580 tons as ore. Totals for preceding years were: 1941, 34,478 tons; 1940, 19,306 tons; 1939, 16,213 tons; 1938, 11,550 tons; and 1937, 9,253 tons.

WORLD ASPECTS OF ZINC INDUSTRY

The war continued to necessitate strict censorship regarding base-metal statistics from many countries. Although official zinc production figures were not, for the most part, available, some general information did filter through. The Bureau of Mines estimated that in 1942 the world mine production of zinc totaled about 2,044,000 short tons (recoverable zinc content) and that zinc smelter capacity amounted to approximately 2,950,000 tons. About 75 percent of the world supply of zinc ore and 54 percent of the total zinc smelting capacity is in the hands of, controlled by, or available to the United Nations. The inability of domestic supplies to pace a greatly expanded smelter capacity has aroused keen interest in all foreign deposits, of which the principal ones are discussed in the following pages.

REVIEW BY COUNTRIES

Argentina.—Practically all the zinc mined in Argentina is from the Aguilar mine of the St. Joseph Lead Co. in the Province of Jujuy, near the Bolivian border. Although no final data for 1942 are available, the reported monthly rate of production from this property alone, amounting to 6,000 to 6,500 metric tons of 54-percent concentrates, indicates that total Argentine output was above the 66,010 tons (36,300 tons zinc content) produced in 1941. Concentrates are transported to Santa Fé for shipment. Exports of this material in 1942 totaled 56,430 tons, all of which went to the United States. Inventories reported on hand at the mine in April totaled 115,000 tons; but by November 30, this stock, available for export, had been reduced to about 93,000 tons. An estimated 1,200 tons of concentrates a month, mostly from other smaller mines, is treated at the Puerto Vilelas smelter.

Australia.—The total production of zinc concentrates in Australia in 1942 was reported to be 387,000 long dry tons averaging about 53 percent zinc. No comparative data are available for 1941. In January 1943 the milling rate was 166,000 long tons of ore a month. The war has hindered increased mining operations by necessitating higher taxation and the transfer of miners to the army and munition industries. Several expansion efforts have been delayed when construction lagged. Diamond drilling has been continued at New Broken Hill and has led to the location of a body of lead ore containing about 16 percent zinc. Production of zinc concentrates was maintained at the Mount Isa Mines, Ltd.

Digitized by Google

Operation of the smelter of the Electrolytic Zinc Co. at Risdon, Tasmania, was hindered by a labor shortage, and production failed to reach full capacity for a short time when an adequate supply of important operating reagent was not available. The Risdon plant produced about 82,000 tons of metal in 1942, but none was available to the United States.

Bolivia.—The mine production of zinc (content in ore) amounted to 10,909 metric tons in 1942 compared with 6,065 metric tons in 1941. All production is exported.

The Huanchaca mine produces most Bolivian zinc by the cut-and-fill method. Output has continued to be small, and no apparent reserves are in sight.

Brazil.—The main deposits of zinc ore (blende) are in the Iporanga region of the State of São Paulo and the Morro do Bule and Januaria regions of the State of Minas Gerais. Reserves have been estimated at about 30,000 metric tons containing 31 to 36 percent zinc, but no large deposits have been found.

Burma.—The fall of Lashio to the Japanese early in March 1942 precluded continued operation by the Burma Corporation of the mines at Bawdwin, and the properties were evacuated by April 25. Reportedly some damage was done to the mines, smelter, and equipment before evacuation, but the extent of destruction and its effect upon subsequent operations by the Japanese is not known. These mines had an annual production of about 45,000 long tons of zinc. The last available information on reserves at this mine (June 30, 1941) gives an estimate of 3,130,200 tons of ore assaying 15.1 ounces of silver, 19.5 percent lead, and 12.1 percent zinc.

Canada.—The war has brought considerable pressure on the Canadian mining industry to expand its output. As a result the 1942 mine output totaled 294,101 short tons (metallic content), an 11-percent gain over the 1941 production of 265,191 short tons. Because Canada has only two refineries—one at Trail and the other at Flin Flon—its ore production exceeds its refinery capacity. There has been considerable interest in building a zinc refinery in Quebec instead of sending the concentrates to the United States. As most of the excess concentrates are shipped to the United States, where the supply of raw material is critical, it is not surprising that the United States has been a guarantor for expansion of mills and other facilities to increase the output of zinc. Plans for a $1,000,000 smelter to be built by the Reeves MacDonald mines south of Trail, British Columbia, and financed by United States funds have been under discussion, but nothing definite has yet materialized.

Of the total zinc mined in Canada, approximately 71 percent is produced in British Columbia (mostly from the Sullivan mine), 20 percent from Flin Flon, and 7 percent from the Noranda district. A large number of small, idle mines were reopened, and extensive diamond-drill prospecting was conducted. An important zinc deposit was found near the Labrador border.

The Sherritt Gordon Mines, Ltd., located a new sulfide-ore deposit containing 1 percent copper and the same amount of zinc. A new zinc-concentrate plant is about completed, and the product will be purchased by the Metals Reserve Company with whom it has contracted to sell 50,000 tons of 50-percent zinc concentrates within a

556250—43——14

Digitized by Google

2-year period. Development work in the zinc deposit at Calumet Island was speeded up, owing to the demand for concentrates for smelters in the United States. The New Calumet expected to "tune up" its new 300-ton zinc-lead concentrator before the end of December. The Golden Manitou mine is constructing a 600-ton-a-day zinc concentrator. By October the Hudson Bay Mining & Smelting Co. had enlarged its plant to 6,200 tons daily capacity. A new shaft allows a higher metallic content ore to be drawn below the 2,250 level in the southern section. Zinc is recovered from a 300,000-ton residue pile averaging 23 percent zinc. Residues are treated with sodium chloride, and the zinc is roasted to yield zinc oxide. The company is selling its excess zinc to the United Kingdom at pre-war prices, with adjustments for increased costs. This same company has proved an important copper-zinc ore body at Schist Lake. Emergency Metals, Ltd., is equipping the Mandy mine with a 200-ton concentrating plant to treat an estimated 180,000 tons of ore averaging 20 to 38 percent zinc, 5 to 8 percent copper, and $5 in gold and silver per ton.

As of June 13, 1942, all imported zinc spelter and zinc in blocks, pigs, bars, or rods has been exempted from customs duty. According to the Department of Munitions and Supply, approximately 95 percent of Canada's entire supply of zinc is devoted to essential and war uses, compared with 75 percent in 1941 and 36 percent in 1940.

Japan.—There are no known zinc deposits of commercial importance in Japan proper, but extensive ore bodies are reported in Chosen. Japan's estimated smelter output in 1941 was 65,000 metric tons. In April 1943 Japan captured the Bawdwin lead-zinc mines of the Burma Corporation, which are capable of supplying 45,000 (long) tons of zinc a year. During 1942 a trade agreement was made with French Indo-China in which Japan will help develop the zinc deposits in that country.

Mexico.—Mine output of zinc in Mexico increased 22 percent from 154,996 metric tons (metal content) in 1941 to 189,278 metric tons in 1942. The most important event in 1942 was the Bateman-Juarez-Tellez agreement among the Metals Reserve Company, the State Department, and the Mexican Government, whereby the Metals Reserve Company contracted to buy 200,000 tons of zinc at 8.25 cents per pound each year for the duration of the war and extendible by mutual agreement after the war. Mexico agreed to stabilize taxes on zinc, freeze freight rates, and hold in abeyance certain clauses in the labor laws. In spite of this agreement labor difficulties appeared, and at the end of the year the miners were threatening to strike for a 25-percent wage increase. On December 23 a reciprocal trade pact between Mexico and the United States reduced the duty on slab zinc and zinc in ore to 50 percent of the amount set by the United States Tariff Act of 1930. The new rate places the tariff on slab zinc at $0.875 cents a pound and zinc in ore and concentrates at $0.750 cents.

The American Smelting & Refining Co. expanded its mining operations at Xichu, Tecolote, Taxco, and San Carlos. Old zinc mines in the Taxco district are being reopened by American Smelting & Refining Co. and Eagle Picher Lead Co. The Sociedad Cooperativa Minera "El Bote," S. C. L., at El Bote is treating 400 tons of lead-zinc ore a day. Crude-ore production of five principal mines in the Chihuahua district increased in 1942 despite the fact that Potosí Mining Co. exhausted its main ore body after nearly 100 years operation. Nearly

Digitized by Google

all the cooperative mining companies reverted to private ownership and operation in 1942. It is reported that a large zinc deposit has been discovered in the Nacozari-Pilars district. The Moctezuma Copper Co. will treat the ore.

Inadequate transportation facilities have continually handicapped the movement of materials and are a limiting factor in further mine expansion.

The Federal Power Commission granted permission to export Texas natural gas to the Rosita smelter of the American Smelting & Refining Co. It is expected that this move will boost zinc production at the only zinc smelter in Mexico an additional 2,400 to 4,800 tons per year.

North Africa.—The principal zinc deposits in North Africa are in the Province of Constantine, Algeria, where the ores—calamine, sphalerite, and galena—occur chiefly as replacement deposits in limestone.

Deposits of ore are known in Tunisia north of Béja and Tunis, and south of Tunis is the Zaghouan concession containing calamine and lead ore. In this same vicinity at the Djebel Ressas concession zinc is mined in conjunction with lead. In the West lies the Sakiet-Sidi Youssef concession, south of Ghardimaou. It is reported that an electrolytic zinc plant was built in 1931 near Touireuf, but there is no record of its ever having operated. The output in Tunisia has fallen off considerably in recent years, largely owing to the depletion of known reserves.

The following table from Mineral Industries of North Africa, Special Supplement to Confidential Series 7, Mineral Trade Notes, lists the production, shipments, and stocks of zinc concentrates, in metric tons, from January 1 to May 1, 1942.

	Production	Shipments	Stocks
Tunisia	840	368	1,972
Algeria	459	4,300	13,091
Morocco	403	800	5,511

Production of concentrates, available to the United Nations since the successful conclusion of the North African military campaign late in 1942 and the first months of 1943, is reportedly being shipped to the United Kingdom for treatment.

Newfoundland.—In spite of a labor shortage that prevented capacity operations, 94,114 short tons of zinc concentrates averaging 53-percent zinc were produced in 1942. In addition 6,564 tons of zinc were recovered in lead and copper concentrates. The comparative figures for 1941 were 116,836 tons of 52-percent zinc concentrates and 8,745 tons of zinc recovered in lead and copper concentrates.

Norway.—Owing to the difficulty of obtaining raw materials, only 3,250 tons of zinc metal were produced from January to September 1942, as against 46,000 tons in the whole year of 1939. In addition to Norwegian ore some Finnish and Swedish ore was used.

Northern Rhodesia.—At Broken Hill, Rhodesia, the Rhodesian Broken Hill Development Co., Ltd., operates the most important zinc mine in Africa. The ore contains 30 to 55 percent zinc plus lead and is associated with vanadium-bearing material.

Digitized by Google

Peru.—In 1942 the mines in this country produced 51,263 metric tons of 58-percent zinc concentrates, a substantial increase over the 1941 total of 40,800 tons containing 23,700 tons of extractable zinc. Zinc mining continued to be largely controlled by the Cerro de Pasco Copper Corporation which owns a zinc deposit in central Peru containing ore reserves estimated at 10,000,000 tons containing 17 percent zinc, 6 percent lead, and 6 ounces of silver per ton. The output from the Cerro de Pasco Casapalca mine, which decreased from 15,877 tons of concentrates in 1940 to 13,550 tons in 1941, probably was smaller in 1942. This mine has a flotation plant with a daily capacity of 800 tons. The Huaron mine of the Cie de Mines de Huaron is now producing at the rate of nearly 1,270 tons of 60-percent concentrates a month. In 1943 Cerro de Pasco should finish a new 800-ton daily capacity concentrator, under construction. The smelter at Oroya produces about 800 tons of refined zinc annually which is consumed in South America. Peruvian exports in 1942 were 247 metric tons of zinc in ore, 25,220 tons in concentrates, and 942 tons of refined zinc.

Spain.—Three mines and one smelter were reported operating in 1941. Output of zinc concentrates in 1941 was estimated at 73,000 metric tons. The monthly production rate of zinc concentrates early in 1943 was between 5,500 and 6,000 tons, and the stocks on hand available for export were about 15,000 tons containing 58 percent zinc and 7,000 tons containing 52 percent zinc. The Cie Royale Asturienne des Mines enlarged its plant and installed a special furnace to produce high-grade zinc.

GENERAL SUMMARY

Activity in the pigments industry as a whole was sharply curtailed in 1942 from the rate that prevailed in 1941. This recession was due not to failure of demand but rather to restrictions in supplies of metal, scrap, and ores early in the year; to curtailment in the use of shipping drums, cans and other containers, brushes, drying oils, and other materials, as the year advanced; and also to conditions that revolutionized whole industries, such as the automobile industry—one of the principal users of pigments. Another deterring factor was the regulation of the Office of Defense Transportation requiring that all shipments by rail be in full carlots or at least up to the full marked capacity of freight cars.

Supplies of zinc and lead metal were restricted throughout the year, but as increasing amounts of lead became available from a record rate of importation, limitations regarding its use were eased in November. Large-scale production of ilmenite began in New York in August, greatly changing the outlook concerning supplies of crude materials for the competitive titanium-pigment group. As a result, restrictions on titanium pigments were lifted in December. The restrictions, nonetheless, had been responsible for what was probably the only noteworthy set-back thus far to the steady advance of this group of pigments.

Consumption of the lead oxides for storage-battery manufacture in 1942 was considerably below the record quantities used in 1941, but except for that year it was higher than ever before. The amounts of zinc oxide and lithopone used in the manufacture of rubber dropped sharply. The outlook for future needs for this purpose is clouded by inability to gage requirements for the manufacture of synthetic rubber. The use of pigments in paints also fell sharply in 1942, except for red lead, which established a new high record. Zinc sulfate for paints and varnish processing was also consumed at a new high rate. Curtailment in the use of pigments by the ceramics industry was marked. On the other hand, agricultural use of zinc sulfate established a new high record in 1942.

According to the F. W. Dodge Corporation, new building construction in 1942 attained a new high record rate, exceeding the previous

Digitized by Google

record by 25 percent. The Lumber and Lumber Products Division of the War Production Board anticipates a noteworthy reduction in the number of board feet required by the Nation in 1943 as compared with 1942, or 31,100,000,000 compared with 40,300,000,000. The peak of war construction at army cantonments, drydocks, airports, and shipyards obviously has passed. In 1942 paint materials were largely used to fill Government needs. In its January 11, 1943, issue the Oil, Paint and Drug Reporter estimated that by fall of 1942 the Government was taking approximately 60 percent of total paint materials compared with 25 percent in 1941 and 5 percent in 1940. The large proportion of steel-construction paint requirements is indicated in part by the new high-record use of red lead in paint in 1942. This pigment is the only one in the group covered by this report that showed increased use for paint manufacture; it is well-known for its use in steel-construction paints.

During and after World War I the chemical industry in the United States made great progress. Dr. J. S. Long [1] says that the American paint industry will emerge from World War II independent of the importation of basic commodities from foreign countries. Many of the new products and processes developed since the start of the war have advantages over those used before that time.

The flexibility of the paint-mixing industry will be tested further by the recent (April 1943) amendment to War Production Board Order M–71 of the Fats and Oils Section of the Department of Agriculture, which reduced this trade's quota of linseed oil and of all other drying oils not required immediately for direct war effort and not already embraced in the edible and potential food categories from 60 to 50 percent of the average 1940–41 usage for the second quarter of 1943. Original Order M–71 (effective October 1942) cut chemical and vegetable oils to 70 percent. In a mimeographed release on conservation in the use of linseed oil in paint, Hickson [2] pointed out that linseed oil is the most widely used drying oil in the paint industry and that about 79 million gallons were consumed in 1940 and about 109 million in 1941, of which 75 to 80 percent was used in the paint and varnish industry. Consumption in 1942 was considered to have been higher than in 1940. Hickson said:

> Nearly all the linseed oil used in the United States is manufactured there, but in 1940 more than one-third of the 31 million bushels of flaxseed required was imported, mainly from Argentina. Under present conditions practically no flaxseed is imported from South America. At the same time there have been new demands for the oil, in part to meet the needs of our Allies, and in part to replace other imported oils such as tung (China wood oil) and perilla oils that were used previously.

Adding to the list of paint components whose need as food material is considered greater than their desirability for paint and other industrial uses, the War Production Board has placed processed industrial casein under allocation control under Order M–307.

In connection with the container problems that developed during the year, an article by Lahey [3] probably will be of interest. Several papers on packaging problems were read at the 14th Annual Pack-

aging Conference in New York early in April and were reviewed briefly in the April 1943 issue of Chemical Industries (p. 482).

The increasing use of fiber drums, wood barrels, glass bottles, and wood boxes, as well as the exercise of great care in handling steel drums already in use in the industry, have tended to offset container difficulties.

Recently released data on the pigments industry in Canada in 1941 show that in that year the industry was at record levels there, as well as in the United States. The following statistics on the short tons used in manufacturing in 1941 (1940 in parentheses) should be of interest: White lead (dry) 2,164 (1,642), white lead in oil 714 (648), basic sulfate white lead 111 (64), litharge 729 (492), red lead 648 (597), zinc oxide (pure) 1,589 (1,680), zinc oxide (leaded) and zinc leads 2,255 (2,087), and lithopone 10,538 (8,194).

Through the Reciprocal Trade Agreement with Mexico, signed in December, the rate of duty on zinc oxide and on leaded zinc oxide containing not more than 25 percent of lead was reduced to 1/10 cents a pound for oxide in dry form and 1½ cents a pound for that mixed with oil or water. The duty on zinc sulfate was cut to ½ cent a pound.

Salient statistics of the lead and zinc pigments industry of the United States, 1925–29 (average) and 1938–42

PRODUCTION

In this report, sales are used as presenting a more accurate picture of the industry than production, partly owing to the lack of statistics covering inventories at the beginning and end of the year. One factor is that at times materials classified as one item for production have been sold later under another description. Thus, sales figures afford a more accurate measure of pigments as they go into consumption

Digitized by Google

channels. Moreover, pigments produced under one classification at a plant are sometimes employed at the plant of another company for blending into another product covered by the lead and zinc pigments canvass. To prevent duplication, the Bureau of Mines attempts to count the product only in the form in which it enters actual use. Basic lead sulfate used in the manufacture of leaded zinc oxide presents the principal problem in this connection. It is included in the statistics in this report at the leaded zinc oxide stage, at which point it enters use in paints. Some other blending is done; but it does not affect large amounts, and—insofar as possible—the duplication involved is eliminated. Production figures are employed in this report in calculating the metal content of pigments and salts in the section on Raw Materials Used in Manufacture of Lead and Zinc Pigments and Zinc Salts. Pigments used by producers in manufacturing products at their own plants are considered here as sales.

The total value of sales of lead and zinc pigments in 1942 was 18 percent below 1941, falling from $85,782,000 to $70,178,000. It was, however, higher than in the 11 years before 1941. The higher average prices generally received for the commodities covered by this report were responsible for the smaller drop in total value as compared with that in the total quantity of the products.

Lead pigments.—In 1941 litharge, red lead, and white lead (dry) had reached new all-time peaks. The declines in these pigments, as well as in others in the lead group, in 1942 may be ascribed, in part at least, to artificial factors—those other than the actual demand. Under the influence of the heavy Government construction program red lead made the best showing of any pigment covered by this report; total sales fell only 10 percent compared with a 34-percent decline for dry white lead, the other extreme in activity among the important pigments. Sales of both red lead and litharge in 1942 exceeded those in all other years except 1941 and were 17 and 8 percent over the averages for 1925–29. White lead in oil decreased 18 percent from 1941, making a better showing than other lead pigments except red lead, but it continued below all others in its relation to other earlier years. Average values received by producers for all lead pigments showed gains in 1942 that ranged, except for the small-tonnage orange mineral, from $9 a ton for white lead in oil to $32 for blue lead sulfate. The lead-pigment group decreased 23 percent in total quantity and 15 percent in total value from 1941.

Zinc pigments and salts.—In the zinc-pigment group leaded zinc oxide established a new high record in 1941. It dropped 30 percent in 1942 but remained above all previous years except 1941. This pigment has been increasingly popular in recent years, and another factor that permitted a better than average record in 1942 was that it was made almost entirely from ores, supplies of which were not as short as of either metal or scrap (other sources of zinc in pigments). Zinc oxide (lead-free) sales were down 33 percent from 1941. Stringent supplies of zinc metal and scrap have had a marked effect on the production of this pigment. Sales of lithopone also were lower than in 1941, having fallen 22 percent. Altogether zinc pigments decreased 28 percent in total quantity in 1942, but they dropped only 21 percent in total value because producers of all types received higher per-ton average prices.

Sales of zinc chloride totaled 52,374 tons (50° B.) in 1942. Comparable data for a number of earlier years are not available. The figures for 1942 include the equivalent zinc chloride content of chromated zinc chloride and zinc ammonium chloride sold.

Except for the high record quantity for 1941, sales of zinc sulfate were at peak levels in 1942. The total for 1942 lagged 25 percent behind 1941 which, however, was 61 percent above the previous record, attained in 1940.

CONSUMPTION BY INDUSTRIES

White lead.—Sales of dry white lead declined 34 percent from 1941, and the "in oil" variety fell 18 percent; the total was 26 percent below 1941 and 46 percent less than the 1925–29 average. The predominant use of both classes of product is in the manufacture of paints, and 92 percent was so used in 1942.

Distribution of white lead (dry and in oil) sales, 1938–42, by industries, in short tons

Industry	1938	1939	1940	1941	1942
Paint	95,018	92,380	73,137	100,665	76,837
Ceramics	1,918	1,767	3,029	3,704	1,812
Other	3,277	4,282	4,396	8,631	4,990
	100,213	98,429	80,562	113,000	83,639

Basic lead sulfate.—Basic lead sulfate also goes mainly into paints, either directly or as a component of leaded zinc oxide. The statistics for basic lead sulfate do not include the quantity used for blending into leaded zinc oxide, the amount so used being accounted for under the latter pigment. In 1941 the use of basic sulfate in the manufacture of leaded zinc oxide reached a peak total of 12,000 tons; in 1942 it amounted to 6,000 tons.

Distribution of basic lead sulfate sales, 1938–42, by industries, in short tons

Industry	1938	1939	1940	1941	1942
Paints	5,024	5,170	5,593	9,285	7,733
Rubber	91	140	128	200	89
Storage batteries	3	4	4	8	----
Other	683	224	475	877	588
	5,801	5,538	6,200	10,370	8,410

Red lead.—This pigment receded from its peak performance in 1941 but maintained a high rate of activity in the face of more serious declines all along the line. Sales in 1942 were 10 percent below 1941 but, except for that year, were the highest ever recorded, surpassing even the heavy construction period in the prosperous twenties. An important reason for the favorable record is the performance of this pigment in construction paints. Red lead is used principally in the manufacture of storage batteries. Its use for this purpose was below the amounts so consumed in 1939, 1940, and 1941, whereas sales for paint manufacture were at new high record levels in 1942. In 1939–40 paint manufacture took 28 percent of the total red lead sold, whereas in 1941 and 1942 it took 37 and 43 percent.

Distribution of red lead sales, 1938–42, by industries, in short tons

Industry	1938	1939	1940	1941	1942
Storage batteries	19,057	24,709	26,718	27,405	23,545
Paints	8,698	11,421	11,949	20,130	21,017
Ceramics	655	1,123	1,117	1,593	939
Other	1,773	2,723	2,416	4,710	2,868
	30,183	39,976	42,200	53,838	48,369

Orange mineral.—This pigment is produced in very small quantities. The manufacture of ink has been its principal application in recent years. Restrictions were placed on its use for this purpose by the War Production Board, limiting consumption in the second quarter of 1942 to 70 percent of that used in one quarter in 1941. The above order was withdrawn in August.

Distribution of orange mineral sales, 1938–42, by industries, in short tons

Industry	1938	1939	1940	1941	1942
Ink manufacture	20	64	51	98	93
Color pigments	94	40	18	26	7
Other	13	27	68	122	28
	127	131	137	246	128

Litharge.—Although sales of litharge in 1942 were 25 percent less than in 1941, they were the largest on record, except for that year. Over a period of years the use of litharge in storage batteries has shown an up-trend. Its use for this purpose in 1942 was less than in 1941 but above all earlier years. Consumption of litharge in insecticides was 24 percent less than in 1941, and except for 1938 it had been exceeded in every year from 1937 to 1941, inclusive. The use in ceramics dropped 48 percent in 1942, but the quantity consumed in that year probably had not been exceeded before 1940. Chrome pigments fell 47, oil refining 29, and rubber 13 percent. Consumption of litharge in oil refining was only 4,771 tons in 1942, compared with 13,615 tons in 1929. In addition to the litharge used in the manufacture of batteries, the storage-battery manufacturers themselves make a black or suboxide of lead which they use as a substitute for litharge. Whereas the quantity so manufactured in 1942 (55,000 tons) was below the peak quantity (61,000 tons) in 1941, it equaled the former record level established in 1940. Black oxide figures are not included in the Bureau of Mines totals for litharge.

Distribution of litharge sales, 1938–42, by industries, in short tons

Industry	1938	1939	1940	1941	1942

Zinc oxide.—Zinc oxide production was affected adversely by the scarcity of zinc metal and scrap. Metal and scrap supplies have been restricted for several years; as a result, the proportion of zinc oxide made from ores has advanced sharply. Zinc oxide produced by the American process (from ore) accounted for 58 percent in 1936; it was 64 percent in 1940, 76 in 1941, and 84 in 1942. French process (from metal and scrap) meanwhile accounted for 42, 36, 24, and 16 percent, respectively, in those years. The proportion of French-process oxide made from scrap has also been on the up-trend. It amounted to 22 percent in 1936 and 45 in 1940 and 1941 but dropped back to 40 in 1942.

Total zinc oxide sales declined 33 percent in 1942, the amounts sold for use in rubber and ceramics showing the most severe drops. The paint class performed better than all others.

Supplementary Order M–11–a was amended in May 1942 (effective June 1) to read that each producer of zinc oxide shall set aside from his production each month quantities to be determined from time to time by the Director of Industry Operations, the remainder to be distributed so that each customer would receive an equal percentage of the producer's commitments to him. For some time no zinc oxide has been set aside because of an excess already in the pool.

Distribution of zinc oxide sales, 1938–42, by industries, in short tons

Industry	1938	1939	1940	1941	1942
Rubber	46,266	70,187	70,979	90,429	52,717
Paints	20,884	25,334	23,268	30,304	25,122
Floor coverings and textiles	3,030	5,641	4,752	6,991	5,224
Ceramics	4,908	6,572	6,352	8,596	2,934
Other	4,041	6,818	7,862	12,513	13,680
	79,129	114,552	113,213	148,833	99,677

Leaded zinc oxide.—Sales of leaded zinc oxide declined 30 percent in 1942, which was almost as severe as the drop in sales of zinc oxide (lead-free). On the basis of long-time trends, however, it has fared far better than the lead-free class. Except for 1941, the leaded group was higher than in any other year and was 81 percent above the annual average for 1925–29. The lead-free class, on the other hand, was 35 percent below the 1925–29 average. Leaded zinc oxide is made entirely from ores, and although these supplies were not abundant they were notably larger than those for metal and scrap. Paint consumes virtually all of the leaded zinc oxide made. The figures for leaded zinc oxide include basic lead sulfate used in blending as indicated under "Basic lead sulfate."

Distribution of leaded zinc oxide sales, 1938–42, by industries, in short tons

Industry	1938	1939	1940	1941	1942
Paints	37,348	41,519	44,341	67,472	47,052
Rubber		1		1	
Other	868	1,164	1,021	1,447	1,076
	38,216	42,684	45,362	68,920	48,128

Lithopone.—Lithopone statistics are reported on the basis of the regular lithopone content of high-strength lithopone plus normal lithopone sold as such. Lithopone sales in 1942 held up better than

Digitized by Google

the average for the zinc-pigment group, having fallen 22 percent from 1941; sales for the year 1941 were close to the level for the 1925–29 period. The distribution of lithopone for paints—the principal use—dropped 18 percent in 1942 but was above the record for the total; sales for floor coverings and textiles were 25 percent lower and rubber 70 percent lower. Based on somewhat incomplete information, separation of the 1942 quantities shown in the following table for floor coverings and textiles indicates that 9,600 tons were used for linoleum and felt-base floor coverings and the remainder for coated fabrics and textiles (oil cloth, shade cloth, artificial leather, and similar products). Other sales in 1942 included 3,423 tons for paper and 555 (incomplete) for printing ink. Figures for an additional quantity for printing ink cannot be separated from the totals for paints. The principal item under "other" uses covers exports. One company, at least, has classified part of its exports according to the end use so that the "other" class is too small to cover total exports.

Plant capacity for the production of lithopone was reported to total 182,000 tons at the end of 1942, unchanged from 1941.

Order M–128 of the War Production Board, issued in May 1942, provided for the establishment of a monthly producers' pool in zinc sulfide pigments, of which lithopone is the chief one. By the time the order had been completed, however, the situation had eased, and virtually no use was made of the power provided. The order is being kept on the books should it be needed.

Distribution of lithopone sales, 1938–42, by industries, in short tons

[1] Includes a quantity, not separable, used for printing ink.

The consumption of ordinary-strength lithopone in the manufacture of titanated lithopone (which usually contains 15 percent TiO_2) reached a peak in 1937, when 19,400 tons were so used; this use took only about half of the record amount, or 9,900 tons in 1942. The lithopone figures in the following table are included in the totals for ordinary lithopone in the preceding table.

Titanated lithopone produced in the United States and ordinary lithopone used in its manufacture, 1938–42, in short tons

Year	Titanated lithopone produced	Ordinary lithopone used	Year	Titanated lithopone produced	Ordinary lithopone used
1938	20,100	17,000	1941	16,800	14,100
1939	16,100	13,700	1942	11,700	9,900
1940	18,100	15,200			

Zinc sulfide.—In recent years as many as four plants have reported production of zinc sulfide, but one company has always dominated the production. For that reason the Bureau of Mines is not at liberty to publish the figures for this pigment. Only this one company produced in 1942.

Digitized by Google

Zinc chloride.—Sales of zinc chloride, in terms of 50° B. solution, totaled 52,374 tons in 1942. These figures include the zinc chloride equivalent of zinc ammonium chloride and chromated zinc chloride produced. Comparable data for recent earlier years are not available.

Zinc sulfate.—Although sales of zinc sulfate declined 25 percent from 1941, they were the highest ever recorded, except for that year. One reason for the recent records for this salt is its increasing use for agricultural purposes. This use made noteworthy gains in 1942 as against the declines in most other uses. Much less zinc sulfate was consumed in the manufacture of rayon, chemicals, and glue in 1942 than in 1941, but the amounts so used compared favorably with other years. Consumption of zinc sulfate in paint and varnish processing has been increasing rapidly in recent years, and it reached new heights in 1942 when it rose 35 percent over 1941. Its use as a flotation reagent has also been gaining.

The large quantity of zinc sulfate produced as an intermediate product in the manufacture of lithopone is excluded from the zinc-sulfate statistics.

Distribution of zinc sulfate sales, 1938–42, by industries, in short tons

Industry	1938	1939	1940	1941	1942
Agriculture	1,664	2,168	2,366	3,038	4,123

RAW MATERIALS USED IN MANUFACTURE OF LEAD AND ZINC PIGMENTS AND ZINC SALTS

Lead pigments and zinc pigments and salts are manufactured from a variety of materials, including ore, refined metal, and such miscellaneous secondary materials as scrap and waste from various industrial processes. In 1942, 93 percent of the lead pigments was derived from pig lead and 7 percent from ore. A small part of the ore used was foreign. The proportion for zinc pigments in 1942 was 79 percent from ore, 6 percent from slab zinc, and 15 percent from secondary materials; 9 percent of the ore used was foreign.

Metal content of lead and zinc pigments produced by domestic manufacturers, 1941–42, by sources, in short tons

Source	1941		1942	
	Lead in pigments [1]	Zinc in pigments	Lead in pigments [1]	Zinc in pigments
Ore:				
Domestic	23,951	129,520	15,949	103,445
Foreign	290	2,464	707	9,636
Metal	248,674	15,463	206,680	8,252
Secondary material [2]	400	31,703	2	21,663
	273,315	179,150	223,338	142,996

[1] Includes also lead recovered in leaded zinc oxide.
[2] Zinc ashes, skimmings, drosses, and old metal.

Digitized by Google

The following tables give the source of the metal used in the manufacture of each pigment and salt. Pig lead is employed exclusively, either directly or indirectly, in the manufacture of white lead, litharge, red lead, and orange mineral and is used also in the manufacture of basic lead sulfate. The lead content of leaded zinc oxide made from basic lead sulfate, which in turn was made from pig lead, is credited to pig lead in the table. Zinc oxide is the only pigment in which considerable slab zinc is used. Ore is employed in the manufacture of zinc oxide, leaded zinc oxide, lithopone, zinc sulfate, and basic lead sulfate. A substantial proportion of the zinc in lithopone and most of that in zinc chloride made in the United States are derived from secondary material. A decided increase has been noted in the quantity of secondary zinc consumed in the manufacture of zinc oxide since 1933. The scarcity of zinc metal and scrap in 1942 caused declines in the proportions of zinc oxide made from these two materials in that year.

PRICES

The total and average values reported by producers for lead and zinc pigments are given in the tables in the first part of this report. For all of the lead pigments average values were $9 to $32 a ton higher than in 1941; the small-tonnage orange mineral gained $5. All of them were at their lowest points for the year in January, which coincided with the highest levels attained in 1941. For each pigment, except basic lead sulfate (white), the gains in 1942 amounted to ¾ cent a pound. In general, the high points were reached in the first 2 months, and prices continued at these levels for the remainder of the year and beyond. Litharge did not reach a peak until June. Basic sulfate (white) advanced ¾ cent in April and dropped back ¼ cent in July.

Pig lead, price changes for which are usually followed closely by those for lead pigments, was under ceiling price limitations beginning January 1942. The ceiling price for common lead, delivered New York, was 6.50 cents a pound. Corroding lead and chemical lead were allowed premiums of 0.10 cent a pound.

Average values reported for all zinc pigments sold were also higher in 1942, the gains ranging from $13 a ton for zinc oxide to $8 for lithopone. The average value for zinc sulfate rose $8 a ton in 1942. The voluntary price ceilings on zinc oxide agreed to by producers, following requests in December 1941 from the Office of Price Administration, were given in the chapter of this series for 1941. On the whole, prices throughout 1942 were ¾ cent a pound above those of the previous year. Late in March negotiations were carried on to increase the voluntary ceilings on leaded zinc oxide containing 35 percent or more lead to 7 cents a pound. The proposed increase was caused by advances in the price of basic sulfate, a basic ingredient of leaded zinc oxide. Later in the month the sweeping General Maximum Price Regulation gathered all grades of zinc oxide among other chemicals, oils, paints, and other commodities under its provisions. Prices under the Regulation were not to exceed the highest ones prevailing in March 1942. In June the Office of Price Administration established the maximum price of 7 cents a pound for the leaded grade mentioned above, effective June 22. Later the effective date was moved back to May 11. A premium of ¼ cent a pound was permitted for delivery of oxide in barrels, another ¼ cent for delivery of less than carlots, and an additional ½ cent for delivery in less than carlots to consumers in California, Oregon, or Washington. Price Schedule 80 of the Office of Price Administration, effective February 2, 1942, set a maximum price of 4.25 cents a pound for the normal grade of lithopone.

FOREIGN TRADE [4]

All of the most important items in foreign trade in lead and zinc pigments are in the export classification and cover white lead, red lead, litharge, zinc oxide, and lithopone. Except for the items specified, foreign trade in lead and zinc pigments has little significance. Exports of all of the important pigments in 1942 declined sharply from the previous year but compared favorably with the years immediately preceding 1941. Available data on imports and exports appear in the following tables.

Value of foreign trade of the United States in lead and zinc pigments and salts, 1941–42

	1941		1942	
	Imports	Exports	Imports	Exports
Lead pigments:				
White lead	$389	$419,630	----------	$392,812

GOLD, SILVER, COPPER, AND LEAD IN ALASKA

(MINE REPORT)

By CHAS. W. HENDERSON

SUMMARY OUTLINE

	Page		Page
Summary	219	Markets and metallurgy	222
Calculation of value of metal production	219	Review by regions	223

SUMMARY

Gold recovered from Alaska ores and gravels in 1942 totaled 487,621 fine ounces valued at $17,066,735, compared with 695,467 ounces valued at $24,341,345 in 1941. The value of the gold in 1942, as in 1941, was 99 percent of the total gross value of the gold, silver, copper, and lead produced. The silver, lead, and copper produced were byproducts of gold mining. The number of producing lode mines decreased from 56 in 1941 to 38 in 1942, floating connected-bucket dredges from 47 to 31, and other types of placer operations from 752 to 422.

The outbreak of the war in December 1941 affected Alaska mining enterprises, both large and small, in several ways and, in a broad sense, is virtually responsible for the decrease in metal output of Alaska lode and placer mines. The threat of enemy invasion prompted the expenditure of hundreds of millions of dollars for highways, airfields, pipe lines, Navy bases, Army cantonments, and other construction necessary for the defense of the Territory. The high wages offered laborers on these projects lured many mining men from their positions at the mines and created a serious labor shortage which closed several of the lode mines, kept certain dredging operations from opening in 1942, and forced all mining operations to work short-handed. Dragline operators whose property remained closed or who were unable to finish the 1942 season had no trouble in disposing of their equipment to contractors on Government defense projects.

War Production Board Gold Mining Limitation Order L–208, coming as it did on October 8, had very little effect on metal production in Alaska in 1942, inasmuch as the mining season for all placer mines and dredges and most lode mines usually ends in November. The full brunt of the order will be felt in 1943. All dredging except the Goodnews Bay platinum operations has ceased for the duration of the war. Only three important lode mines were active the first half of 1943, and these were permitted only under limited reprieves.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

Yardage figures used in measuring material treated in placer operations are "bank measure"; that is, the material is measured in the ground before treatment.

The value of metal production herein reported has been calculated at the following prices.

[2] Cubic yards of gravel (average recovered per yard, $0.56).
[3] Includes all types and sizes of placer operations, excluding floating connected-bucket dredges.
[4] Cubic yards of gravel; figures not available.

Mine production of metals from amalgamation and cyanidation mills (with or without concentration equipment) in Alaska in 1942, by regions, in terms of recovered metals

Region	Ore treated (short tons)	Recovered in bullion		Concentrates smelted and recovered metal				
		Gold (fine ounces)	Silver (fine ounces)	Concentrates produced (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)
Cook Inlet-Susitna	32,389	30,705	1,628	1,119	6,844	573	4,200	100
Copper River	1,420	1,703	359	88	353	106	200	
Kenai Peninsula	587	554	154	2	40	28		160
Kuskokwim	([1])	148	35					
Southeastern Alaska	2,770,434	68,094	16,780	1,586	14,353	44,196	37,437	798,849
Yukon River Basin	10,054	14,100	2,972	67	378	469		1,100
	2,814,884	115,304	21,928	2,862	21,968	45,372	41,837	800,209
Total, 1941	4,443,260	165,530	31,823	3,963	33,451	81,697	78,901	1,322,131

[1] Less than ½ ton.

Gold.—Floating connected-bucket dredges recovered 51 percent of the total Alaska output of gold in 1942 compared with 44 percent in 1941. The United States Smelting, Refining & Mining Co., operating seven dredges in the Fairbanks district and two in the Nome district, was the largest producer of gold from this source in the Territory in both years. Placer mines worked by dragline and dry-land dredges, bulldozers, and hydraulic giants, drifting, and sluicing together yielded 21 percent of the total gold in 1942 compared with 27 percent in 1941. A large part of the output from these types of operations came from the Fairbanks, Circle, Council-Bluff, Iditarod (Flat), Fairhaven, Tuluksak-Aniak, and Nome districts. Lode mines contributed 28 percent of the total Alaska output of gold in 1942 compared with 29 percent in 1941. The Alaska Juneau Gold Mining Co. continued to be much the largest producer of lode gold in Alaska.

Silver.—All the silver produced in Alaska in 1942 was a byproduct of gold mining.

Copper.—The output of recoverable copper in Alaska in 1942 came from dry and siliceous ores.

Lead.—Most of the recovered lead output of Alaska in 1942 came from lead concentrates produced at the flotation mill of the Alaska Juneau Gold Mining Co.

Digitized by Google

MARKETS AND METALLURGY

About 95 percent of the gold and 61 percent of the silver produced from Alaska ores and gravels in 1942 were obtained in the form of gold-silver bullion, which was sold finally to the Seattle Assay Office and the San Francisco Mint. As there are no smelters or refineries in Alaska, all the remaining gold and silver produced and all the lead and copper were obtained from high-grade ore and concentrates shipped to smelters and refineries in the States, largely to the Tacoma (Wash.) and Selby (Calif.) smelters. The largest purchasers (or agents) of gold-silver bullion in the Territory and in Seattle (Wash.) in 1942 were: The Bank of Alaska, Anchorage; the Bank of Fairbanks and the First National Bank of Fairbanks, Fairbanks; the First National Bank of Valdez, Valdez; the Miners and Merchants Bank of Alaska, Nome; the Miners and Merchants Bank of Iditarod, Flat; and the Northern Commercial Co., Seattle, Wash. The bullion purchased was either sent direct to the mints or cast into bars for shipping; in many instances the banks acted merely as agents for the lode and placer operations.

Ore-dressing mills active in Alaska in 1942 included the 12,000-ton Alaska Juneau amalgamation-table concentration-flotation mill and and approximately 31 other mills, chiefly amalgamation or cyanidation plants, a few of which have some other supplementary concentrating equipment. With the exception of the Alaska Juneau, no mill had a daily capacity of over 75 tons. Virtually all the lead concentrates produced in 1942 were obtained from concentration by flotation of the dry gold ore of the Alaska Juneau Gold Mining Co. property at Juneau. Most of the small output of copper also came from lead concentrates produced at the Alaska Juneau property. Shipments of concentrates from amalgamation or cyanidation mills having concentrating equipment averaged 7.68 ounces of gold and 15.85 ounces of silver to the ton; concentrates from straight concentration mills averaged 1.58 ounces of gold and 10.54 ounces of silver to the ton. Many mills reported mill heads averaging more than 1 ounce of gold to the ton.

Bullion of Alaska origin deposited at United States Assay Office, Seattle, Wash., during year ended December 31, in fine ounces

REVIEW BY REGIONS

Cook Inlet-Susitna region.—This region, which includes the Iliamna, Valdez Creek, Willow Creek, and Yentna-Cache Creek districts, produced 27 percent of the total gold output from lode mines in Alaska in 1942. There were 7 producing lode mines compared with 10 in 1941.

The Alaska-Pacific Consolidated Mining Co., operating the Independence, Martin, Free Gold, and Ready Bullion mines near the head of Fishhook Creek in the Willow Creek district, continued to be the largest producer of gold in the Cook Inlet-Susitna region and the second-largest producer of lode gold in Alaska. The company 72-ton amalgamation-flotation mill and sorting plant were operated at capacity 7 days a week throughout the year. The ore treated averaged 1.34 ounces of gold and 0.48 ounce of silver to the ton. Because the ore contains scheelite, the War Production Board in November issued a special permit which enabled the company to continue its gold operations until midsummer of 1943. At that time, the exact quantity of scheelite will have been determined and necessary alterations for its recovery will have been made in the mill. The new installation will include 2 sand tables, slime decks, and 16 flotation cells. As the tailings assays from the gold-recovery operations show a scheelite content of 0.5 to 2½ percent, the mill procedure will be first to recover the gold, the tailing to be treated subsequently on tables and finally by flotation to produce tungsten concentrates.

The Willow Creek Mining Co. operated its Lucky Shot, War Baby, and Gold Bullion mines and 60-ton amalgamation-flotation-cyanidation mill on Craigie Creek, 22 miles north of Wasilla, until September 1942, when it ceased operations because of an acute shortage of labor. Methods of ore treatment are described in the Alaska chapter of Minerals Yearbook, 1941.

Other lode-gold producers in the Cook Inlet-Susitna region were the Fern Gold Leasing Co., operating its Fern and Talkeetna group of mines and 30-ton amalgamation-flotation mill; and the Gold Cord Mining Co., operating the Gold Cord lode and 20-ton amalgamation-flotation mill, and Gold Zone Mine, Inc., both of which closed in August because of labor shortage.

Placer operations, using principally hydraulic giants, continued to recover gold from stream and bench gravels. Placer production in the Yentna-Cache Creek district came from property around the Dutch and Peters Hills, part of the southern foothills of the Alaska Range. The productive placer creeks flowing from these hills are tributaries of Peters, Cache, or Granite Creeks. Among the larger producers of placer gold in the district were the Fairview Mining Co., C. M. Reeve & Son, Falls Creek Mining Co., and Talkeetna Mines, Inc. In the Valdez Creek district John E. Carlson worked several placers on Valdez Creek.

Copper River region.—The Copper River region includes the Chistochina, Nelchina, Nizina, Prince William Sound, and Yakataga (including Icy Bay) districts. Cliff Goldmines, Inc., operated the Cliff mine and 24-ton amalgamation-gravity concentration mill on Valdez Bay, 10 miles west of Valdez, until October, when operations ceased owing to inability to obtain sufficient supplies, equipment, and labor. Improvements at the mine in 1942 included installation of an electric hoist, a ventilating fan on the 500-foot level, and a telephone

Digitized by Google

communication system servicing all sections of the mine. In 1942 the property produced bullion yielding 1,617 fine ounces of gold and 338 fine ounces of silver, and 51 tons of gold-silver concentrates containing 78 ounces of gold and 22 ounces of silver. Other producers of lode gold included the Sun Ray Mining Co. and Don C. Preston, both operating in the Prince William Sound district. Yellow Band Gold Mines, Inc., was unable to open its property in the Nizina district in 1942 because of the War Production Board amendment to Order P–56 depriving gold and silver mines of an effective priority rating for obtaining equipment and supplies.

Placer gravels were worked in the Copper River region in 1942 chiefly by hydraulicking and ground sluicing. Larger placer-gold producers included Chititu Mines in Rex Gulch and Dan Creek Placer Mines, Inc., on Dan Creek 25 miles east of McCarthy in the Nizina district.

Kenai Peninsula region.—The Kenai Peninsula region includes the Moose Pass-Hope, Nuka Bay-Homer, and Turnagain Arm-Girdwood districts. Most of the output of lode gold in the Kenai Peninsula region came from the Marigold and Gilpatrick mines near the divide between Quartz and Canyon Creeks in the Moose Pass-Hope district; the Paystreak mine in the Nuka Bay-Homer district; and the Crow Creek Gold Corporation property at the head of Crow Creek in the Turnagain Arm-Girdwood district. Among the producing placers were the Hope Mining Co. on Resurrection Creek and Stetson Placers, Inc., on Stetson Creek in the Moose Pass-Hope district.

Kuskokwim region.—The Kuskokwim region includes the Bethel, Goodnews Bay, McGrath, and Tuluksak-Aniak mining districts. A clean-up of the mill at the Nixon Fork mine, owned and operated by Mespelt & Co., produced a small quantity of gold bullion, which was sold to the Seattle Assay Office.

In the Goodnews Bay district, the Goodnews Bay Mining Co., dredging for platinum, operated its dredge (equipped with 92 8-cubic foot buckets) on Salmon River from April 25 to November 10. The company also produced platinum from its dragline operations on Salmon River. The New York Alaska Gold Dredging Co. operated its two floating connected-bucket dredges (one with 4-cubic foot buckets and the other with 2½-cubic foot buckets) from May 9 to November 14 at its consolidated group of placer claims on upper Tuluksak River in the Tuluksak-Aniak district.

Larger producers of placer gold from dragline land dredge operations included the Marvel Creek Mining Co. and Garrison Co. in the Tuluksak-Aniak district.

Northwestern Alaska region.—A small quantity of placer gold was recovered by sluicing on the Kobuk River in 1942.

Seward Peninsula region.—Mining in the Seward Peninsula region—comprising the Council-Bluff, Fairhaven, Kougarok, Koyuk, Nome, Port Clarence, and Serpentine River districts—was confined to the recovery of placer gold. The region had 14 floating connected-bucket dredges in 1942 (compared with 22 in 1941) and numerous bulldozer, hydraulicking, dragline land dredging, drift mining, and ground-sluicing operations. A total of 4,228,071 cubic yards of gravel containing 52,528 fine ounces of gold and 5,960 fine ounces of silver was handled by the dredges of the region. The average value of the gravel worked by dredges was about 44 cents per cubic yard compared with 47 cents in 1941.

Digitized by Google

The United States Smelting, Refining & Mining Co., in the Nome district, was again the largest producer of gold in the region. The company operated two electrically powered Yuba dredges (one with 134 and one with 112 9-cubic foot buckets) from May 26 to October 15. Gravel washed in 1942 totaled 2,413,450 cubic yards compared with approximately 4,000,000 in 1941.

Arctic Circle Exploration, Inc., operated two dredges, each with 70 4-cubic foot buckets, on Candle Creek in the Fairhaven district and again ranked second in production of gold in the region.

Lee Bros. Dredging Co., third-largest producer of placer gold in the region, operated two Diesel-powered floating connected-bucket dredges (one with 74 and one with 66 buckets) on the Solomon River in the Nome district from June to October.

Castleton & Keenan operated a Washington Iron Works Diesel-powered dredge equipped with 85 2¼-cubic foot buckets on the Kougarok River in the Kougarok district from May 15 to October 6.

Other companies operating floating connected-bucket dredges in the Seward Peninsula region were: The Alaska Placer Co., Camp Creek Dredging Co., and Inland Dredging Co., all in the Council-Bluff district; Dry Creek Dredging Co. and Forsgren Dredging Co., both operating on the Inmachuk River in the Fairhaven district; Fox Bar Dredging Co. in the Kougarok district; and Casa de Paga Gold Co. on Beaver Creek in the Nome district.

Larger producers of gold from placers worked by hydraulic giants, with some additional combination of bulldozers, draglines, and pumping equipment, were: Crabtree & Sullivan in the Council-Bluff district; Mud Creek Mines in the Fairhaven district; Castleton & Keenan, Dahl Creek Mining Co., Gold Bullion, Inc., and Grant Mining Co., all in the Kougarok district; B. F. Gillette, Gabe Johnson & Co., and E. W. Quigley in the Nome district; and Frank L. Rice and Gilbert Fidjeland in the Port Clarence district.

Southeastern Alaska region.—Southeastern Alaska—including the Admiralty Island, Chichagof Island, Hyder, Juneau, Ketchikan, and Windham Bay districts—produced 60 percent of the total lode gold and most of the silver, copper, and lead output of Alaska as a whole in 1942. There were 12 active mines in 1942 compared with 16 mines in 1941.

The Alaska Juneau was the largest producer of silver and lead and was second only to the United States Smelting, Refining & Mining Co. in output of gold in Alaska in 1942. In the Twenty-Eighth Annual Report of the Alaska Juneau Gold Mining Co., for the year ended December 31, 1942, the president's report (dated March 4, 1943) says—

> On October 8, 1942, there was issued by the War Production Board in Washington, "Limitation Order L–208," the purpose of which was to close down "in the shortest possible time" all "nonessential mine" operations, with particular reference to gold mines. The purpose of the order was the freeing of labor for use in mining those metals needed for war purposes. There were certain exceptions embraced in the order which made it possible for the Alaska Juneau mine to continue operating on a limited scale. It so happens also that your company's operations, taken as a single unit, are of such value in the supplying of many indispensable services to the Juneau community and to the military and naval forces located therein, as to far outweigh any benefits that might arise through their discontinuance. The release of manpower contemplated by the order could only be small for the reason that our crew has already become reduced from a normal

Digitized by Google

full production working crew of about 1,000 men to the present crew of 350 men, the employees having been drawn away by higher wages offered in the war industries than the company can afford to pay.

With this curtailed crew it is still possible to make a small operating profit. It may be considered, of course, that operation at this reduced capacity is merely a matter of exhausting our ore reserves to no point, but as against this view it must be considered that a complete shut-down would not only involve a very considerable standby expense but would also result in the loss of many of our key men whose training, experience, and general efficiency is a highly essential factor in the successful operation of the Alaska Juneau mine. If, for some reason arising out of the present emergency, mining had to be discontinued altogether, then resumption at a later date with a crew of men green to the operation and unacquainted with each other, would have a decided adverse effect on the smooth and efficient handling of the property. From all points of view, therefore, it is most fortunate that the operations have been continuous throughout even on a limited scale; although, as far as can now be foreseen, there will be no change in the situation until the present emergency has terminated.

There has been no important change in the mine or in the plant during the past year as, owing to the scarcity of labor, no new work of any kind has been undertaken; in fact, the operations have consisted of merely marking time with all effort being made to prevent an operating loss.

As was stated in the annual report for last year, there has been an attempt made to find profitable mining ventures in the strategic minerals field, and, while much work was done in this direction and many properties examined, nothing worth while has been found. This exploratory work, however, still continues.

During the year some plans were entered into with the Metals Reserve Co., an agency of the Federal Government, for the treatment of Alaska chrome ores in our mill at Juneau, but upon investigation they have decided that the physical obstacles involved did not justify going ahead with these plans, particularly in view of the large increase in the production of chrome from other sources where conditions for cheap operations were much more favorable.

The general superintendent's report (dated February 1, 1943) says—

The present war has greatly interfered with the operation of the mine. During the year 1942, the amount of rock trammed from the mine was 2,765,190 tons as compared to the previous year's output of 4,354,770. The difference represents a decrease of about 4,400 tons per day on the average. The North ore body furnished 20 percent of the year's tonnage, the South ore body 23 percent, while the Perseverance division of the mine supplied 57 percent of the total.

During the year 235,750 pounds of powder were used in blasting powder drifts, or 0.09 pound per ton trammed. Total powder consumption for primary and secondary breaking was 0.28 pound per ton trammed in 1942, as against 0.29 pound in 1941 and 0.32 pound in 1940. This gives a tonnage ratio of 3.55 tons of ore per pound of powder in 1942, as against 3.45 tons in 1941.

The past year also saw a great reduction in the amount of development and preparatory mining work. During the year, however, the main haulage level on 13 level in the Deep North ore body was completed between the main shaft and the principal oreway. All exploratory work has been discontinued.

In June the operation of the mine and the mill was reduced from three shifts per day to two shifts per day. In December, however, the mill was again operated on all three shifts, mainly in order to make more efficient use of the company's hydroelectric power and to conserve fuel oil.

Construction work.—The only construction work of importance during the year was that done in connection with a plan for the beneficiation of chrome ore in our mill. This work consisted of building conveyors, aerial tramway, bins, etc.

Labor.—All during the year there was a great shortage of both skilled and unskilled labor in the various departments. The labor turn-over was high, and the actual loss of employees was great. The number of employees at the beginning of the year was 866 as against 478 at the end of the year. The average labor turn-over for the year was over 100 percent.

In May 1942, wage increases amounting to about 12 percent were incorporated into the agreement with the Juneau Mine & Mill Workers Union.

The average wage per day in 1942 was $7.67 as against $7.17 in 1941.

The overall cost per man per day was $11.93 in 1942, as compared to $11.14 in 1941.

Digitized by Google

The Hirst-Chichagof Mining Co. on Chichagof Island, 65 miles northwest of Sitka, operated its mine and 35-ton amalgamation-flotation mill continuously until closed on October 15 by the Gold Mining Limitation Order. The mill treated 3,584 tons of gold-silver ore, which yielded bullion containing 3,716 fine ounces of gold and 809 fine ounces of silver, and 110 tons of gold-silver concentrates containing 726 ounces of gold, 331 ounces of silver, and a minor amount of copper. Bullion produced was sent direct to the Seattle Assay Office, and the concentrates were shipped to the Tacoma (Wash.) smelter.

The Chichagof Mining Co. at Klag Bay on Chichagof Island shipped gold-silver concentrates and gold bullion recovered from milling operations conducted in 1941. The company did not operate the mine or mill in 1942.

The output from other lode mines in the region was small and included production from the Williams mine in the Admiralty Island district; the Leroy and Rainbow lodes in the Juneau district; and the Gold Standard, Lucky Jack, Jessie, Dawson, and N & T mines in the Ketchikan district.

The Riverside tungsten mine in the Hyder district, owned and operated by J. H. Scott, shipped lead-silver-gold concentrates to the Bunker Hill & Sullivan smelter at Kellogg, Idaho. Tungsten concentrates stock-piled for a number of years because of the Jones Act of 1920 requiring shipments of concentrates to be made in American vessels are now being sent to the United States on Canadian boats owing to a recent Department of Commerce ruling.

Sluicing in the Juneau district in 1942 recovered small amounts of placer gold.

Yukon River Basin region.—The Yukon River Basin region includes the following mining districts: Bonnifield-Nenana, Chandalar, Chisana, Circle, Delta River, Eagle, Fairbanks, Fortymile, Goodpaster, Hot Springs, Hughes, Iditarod, Innoko, Kantishna, Koyukuk, Marshall, Rampart, Ruby, Tolovana, and Yukon Flats. The region yielded 75 percent of the total output from connected-bucket dredges in Alaska during 1942; it again ranked third in gold recovered from lode mines.

Fifteen floating connected-bucket dredges were operating in the region in 1942 compared with 22 in 1941.

The United States Smelting, Refining & Mining Co., operating seven floating connected-bucket dredges in the Fairbanks district, was much the largest producer of gold and silver in the Yukon River Basin region. The company operated two 10-cubic foot Bethlehem dredges (with 111 and 93 buckets, respectively), one 10-cubic foot Yuba dredge (with 106 buckets), one 3-cubic foot Yuba dredge (with 68 buckets), and three 6-cubic foot Bethlehem dredges (with 78, 78, and 68 buckets, respectively); all the dredges were electrically operated. Other equipment used (chiefly for removing overburden) included 315 Joshua Hendy hydraulic giants, one 8- to 12-cubic yard electric-powered Bucyrus 10–W dragline, and one oil-burning caterpillar bulldozer. Of the dredges operated in 1942, two were on Cleary Creek, two on Goldstream Creek, and one each on Cripple, Ester, and Pedro Creeks.

The Thirty-Seventh Annual Report of the United States Smelting, Refining & Mining Co., for the year ended December 31, 1942 (dated March 23, 1943), says—

Digitized by Google

At the Alaska gold properties favorable development continued but the operations were shut down by Government order in the fall of 1942. Maintenance crews are keeping the dredges and plants in repair and in readiness for resumption of operations when that becomes possible. Some of the buildings and equipment have been leased to the Government and revenues will help to defray some of the shut-down expenses.

In the Circle district three dredges were again active in 1942. Alluvial Golds, Inc., operated its W. W. Johnson Co. dredge (with 72 4-cubic foot buckets) on Woodchopper Creek from May 27 to October 12. Gold Placers, Inc., operated a similar type of dredge equipped with 60 4-cubic foot buckets on Coal Creek from June 1 to October 13. The C. J. Berry Dredging Co. operated its steam-powered dredge (with 58 3-cubic foot buckets) and handled about 239,800 cubic yards of gravel.

In the Fairbanks district the Brinker-Johnson Co. operated its W. W. Johnson dredge (with 78 4½-cubic foot buckets) on Caribou Creek from May 11 to October 4, 1942.

The North American Dredging Co. operated its Washington Iron Works dredge (with 70 3½-cubic foot buckets) on Otter Creek from June 1 to October 29. The J. E. Riley Investment Co. also operated a dredge on Otter Creek.

Two dredges were active in the Innoko district in 1942; the Ganes Mining Co. and Moss & Larson Mining Co. operated one each on Ganes Creek.

All types of placer operations—other than floating connected-bucket dredges—were to be found throughout the Yukon River Basin region in 1942.

The largest producers of placer gold in the Bonnifield-Nenana district in 1942 were Dan Cole and the Gold King mine, both bulldozer and hydraulic operations.

Among the larger producers in the Circle district using hydraulic giants and bulldozers or draglines with screening and sluicing plants were: The Berry Holding Co., John Frasca & Co., Half Dollar Mining Co., Switch Creek Mining Co., and Deadwood Mining Co.

In the Fairbanks district Helmer Johnson handled approximately 23,000 cubic yards of gravel with two hydraulic giants and a bulldozer at his placer on upper Cleary Creek. The Wolf Creek Mining Co. operated its dragline and washing plant on Wolf Creek and continued to be an important producer of placer gold. The Faith Creek Mining Co. on Faith Creek and the Fish Creek Mining Co. on upper Fish Creek recovered placer gold by hydraulicking, bulldozing, and sluicing. Other important producers in the Fairbanks district included the Alder Creek Mining Co., Brown & Reeves, A. A. Zimmerman, and Fred Parker.

The Wade Creek Dredging Co. confined its operations in 1942 to hydraulicking and bulldozing gravels at its claims on Uhler and Jack Wade Creeks from May 1 to September 12.

Larger placer operators in the Hot Springs district were the Cleary Hill Mines Co., operating six hydraulic giants, one dragline, and two bulldozers on Sullivan and Eureka Creeks; J. R. Frank & Co., hydraulicking on Pioneer Creek; and Gold Mines, Ltd., operating a bulldozer and dragline on American Creek.

In the Iditarod district the Awe Mining Co., Granite Mining Co., Hatten, Bauquier & Turner, Peter Miscovich & Sons, Moore Creek

Digitized by Google

Mining Co., Turner & Remington, and Uotila & Ogriz all operated during the 1942 season, using draglines, bulldozers, and hydraulics.

Hard & Uotila operated their hydraulic, bulldozer, and dragline equipment from April to October on Beaver and Ophir Creeks. Degnan & Rosander and the Cripple Creek Mining Co. operated similar equipment on Little Creek and Cripple Creek, respectively. Other large placer operators were McFarland & Hartley, S. R. Paulson, and Savage & Matheson.

On Caribou Creek in the Kantishna district Caribou Mines handled 125,925 cubic yards of gravel from June 15 to September 28, using a 1½-cubic yard dragline, washing plant, and stacker mounted on crawlers.

The principal producer of gold in the Koyukuk district in 1942 again was Repo & Schwaesdall, operating hydraulic giants, bulldozers, and a dragline on Myrtle Creek.

The Yukon Mining Co. did sluicing on bedrock from June 1 to September 15 on Buster and Windy Creeks in the Marshall district. Johnston & Ostnes and the Willow Creek Mining Co. worked gravels along Willow Creek with hydraulics, bulldozers, and draglines.

Other large producers among these types of placer operations in the Yukon River Basin region in 1942 were the Long Creek Mining Co. and the Midnight Mines, Developing & Operating Co., in the Ruby district, and the Amy Creek Mining Co., A. S. Warwick, and Parker & Son in the Tolovana district.

Lode mining in the Yukon River Basin region produced 14,478 fine ounces of gold and 3,441 fine ounces of silver in 1942 compared with 16,763 ounces of gold and 8,114 ounces of silver in 1941.

The leading producer of lode gold in the region in 1942 was Cleary Hill Mines, Inc., operating the Cleary Hill mine and amalgamation-flotation mill in the Fairbanks district 27 miles northeast of Fairbanks. The United States Smelting, Refining & Mining Co. operated its McCarty mine on Fairbanks Creek until October 15; the mine is equipped with a 10-ton amalgamation mill. The Hi Yu Mining Co. continued small-scale operations at its Hi Yu mine and 50-ton amalgamation mill on Fairbanks Creek until July, when the property was closed because of inadequate labor. Additional production of lode gold in the Fairbanks district in 1942 came from the Clipper, Rambone, Lookout, Oregon, and Wyoming claims.

In the Kantishna district the Red Top Mining Co. operated its Banjo mine and 50-ton jig-, table-, and flotation-concentration mill until September, when a shortage of labor forced operations to cease.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN ARIZONA

(MINE REPORT)

By G. E. Woodward and Paul Luff

SUMMARY OUTLINE

	Page		Page
Summary	231	Mining industry	237
Calculation of value of metal production	232	Ore classification	238
Mine production by counties	236	Metallurgic industry	238
		Review by counties and districts	243

SUMMARY

The total value of the output of recoverable metals from mines in Arizona was $114,525,600 in 1942 compared with $97,638,310 in 1941—an increase of 17 percent (see fig. 1); it was the greatest value since 1929, when the total was $155,567,133. Both the quantity and value of copper and zinc increased substantially in 1942; the quantity of lead decreased, but the value increased owing to the higher average price of the metal. The total value of the copper was $95,199,654—a 24-percent gain over 1941; lead, $1,979,448—an 11-percent gain; and zinc, $3,445,092—a 39-percent gain. The value of the gold was $8,877,785—a 20-percent loss; and silver, $5,023,621—a 6-percent loss. The gold production represented 8 percent of the State total value, silver 4 percent, copper 83 percent, lead 2 percent, and zinc 3 percent. The value of the metals recovered from copper ore was $103,195,449 in 1942, or 90 percent of the State total. The output of copper was greater in 1942 than in any year except 1929, when it was 830,628,411 pounds, and the output of zinc exceeded the record output of 1941.

Production of copper, lead, and zinc (especially copper) in Arizona in 1942 was affected by several factors: Premium prices for copper, lead, and zinc; labor shortage; difficulty in obtaining sufficient supplies; disputes on rates of pay; and inexperience and inefficiency of employee replacements. The Metals Reserve Co. announced that, effective February 1, 1942, premiums of 5 cents a pound for copper and 2¾ cents a pound for both lead and zinc would be paid for these metals produced in excess of certain fixed basic quotas. Each mine has its basic quota fixed according to 1941 production. Also, effective December 1, 1942, the Metals Reserve Co. announced that it would pay an additional premium of 2¾ cents a pound for lead and two additional premiums of 2¾ cents a pound for zinc for over-quota metal production. Special contracts were negotiated during the last quarter of the year with Metals Reserve Co., which provided for the mining of marginal or low-grade copper ores from certain areas of some of the large Arizona copper producers.

Digitized by Google

A labor shortage began in April at the mines, mills, and smelters in Arizona, resulting from men leaving to take jobs on Government construction projects and in war industries where abnormally high wages were paid. This shortage became so acute during the summer that the output of ore from some of the mines was curtailed as much as 50 percent. The seriousness of the condition was recognized by the War Department, which in October furloughed about 1,100 soldiers for service in Arizona mines. This action tended to relieve the shortage but did not insure an adequate labor supply. The labor shortage at the Morenci open pit was partly relieved by the employment of a number of Navajo Indians.

The Government gold-mine closing order affected some of the gold producers in Arizona, but a majority of them had shut down several months before the order was issued.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1938–42

Year	Gold [1]	Silver [2]	Copper [3]	Lead [4]	Zinc [4]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1938	$35.00	[5] $0.646+	$0.098	$0.046	$0.048
1939	35.00	[6] .678+	.104	.047	.052
1940	35.00	[7] .711+	.113	.050	.063
1941	35.00	[7] .711+	.118	.057	.075
1942	35.00	[7] .711+	.121	.067	.093

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from Jan. 18, 1837, to Jan. 31, 1934, was $20.67+($20.671835) per fine ounce.

[2] Treasury buying price for newly mined silver.

[3] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production but excludes value of foreign copper delivered to Metals Reserve Co. for domestic consumption.

[4] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production.

[5] $0.64646464. [6] $0.67878787. [7] $0.71111111.

Mine production of gold, silver, copper, lead, and zinc in Arizona, 1938–42, and total, 1860–1942, in terms of recovered metals

Year	Mines producing		Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1938	885	329	14,203,164	305,043	$10,676,505	7,479,153	$4,835,008

[1] Includes placer sands treated by dry concentration plants.
[2] A floating washing plant supplied with gravel by a dragline excavator is called a "dragline dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."
[3] Figures for dragline floating dredges include those for dry-land dredges.

Gold.—The output of recoverable gold in Arizona in 1942 was 253,651 fine ounces—a decrease of nearly 20 percent from 1941. Gold from siliceous ores (chiefly dry and siliceous gold ore) declined more than 34 percent and that from zinc-lead ore 38 percent; gold from copper ore increased only 2 percent. Gold from placers decreased from 11,931 to 2,836 ounces; half of the total placer gold in 1942 was recovered by dragline dredging at properties on Big Bug Creek in Yavapai County. The Copper Queen (Bisbee) branch of the Phelps Dodge Corporation continued to be the leading gold producer in Arizona; it was followed by the New Cornelia mine in Pima County, the Mammoth-St. Anthony Limited property in Pinal County, the United Verde mine in Yavapai County, the Goldroad mine (United States Smelting, Refining & Mining Co.) in Mohave County, and the Magma mine in Pinal County; these six properties produced nearly 72 percent of the State total output. Copper ore yielded 57 percent of the State total gold, siliceous ores 37 percent, and zinc-lead ore 3 percent. The chief gold-producing districts in Arizona were the Warren, Ajo, San Francisco, Verde, Old Hat, Weaver (Yavapai County), Pioneer (Superior), and Big Bug.

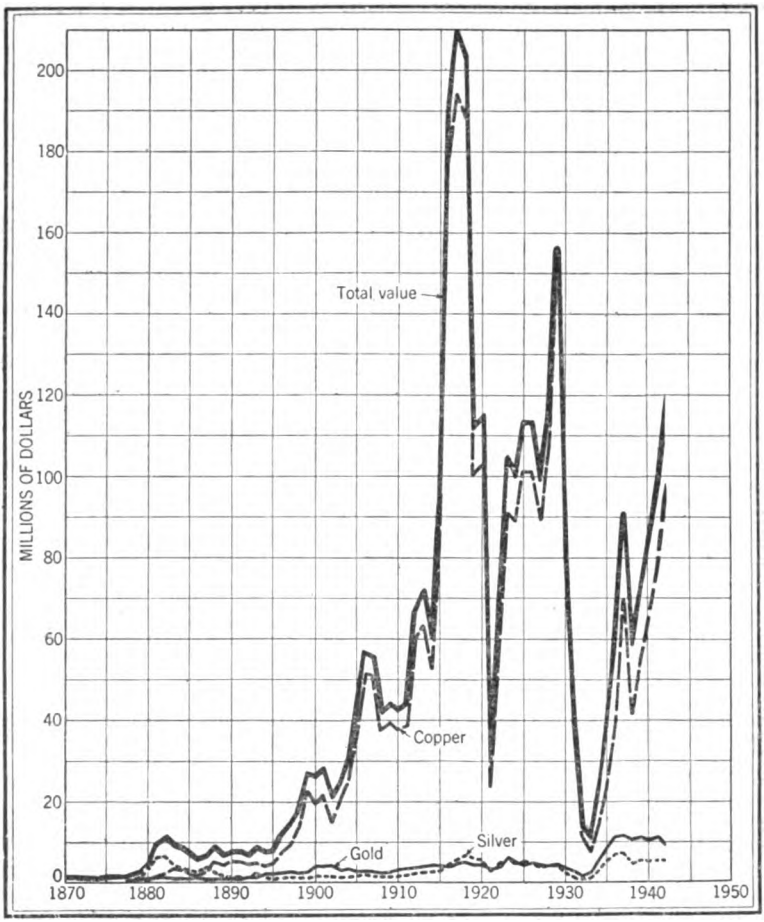

FIGURE 1.—Value of mine production of gold, silver, and copper and total value of gold, silver, copper, lead, and zinc in Arizona, 1870-1942. The value of lead and zinc has been less than $2,000,000 annually, except in a few years.

Silver.—The output of recoverable silver in Arizona in 1942 was 7,064,467 fine ounces—a decrease of 6 percent from 1941. The chief decreases were 270,508 ounces in silver from siliceous ores, 85,554 ounces from zinc-lead ore, 32,237 ounces from zinc ore and zinc-copper ore, and 29,516 ounces from lead ore. Copper ore yielded 71 percent of the State total silver, siliceous ores 13 percent, zinc-lead ore 12 percent, zinc ore nearly 3 percent, and lead ore 1 percent. The Phelps Dodge Corporation continued to be the chief silver producer in Arizona, and its output was 4 percent greater than in 1941; its four properties (Copper Queen, Morenci, New Cornelia, and United Verde) produced 50 percent of the State gold output, 60 percent of the silver, and 56 percent of the copper. Other large silver producers in Arizona in 1942 were the Magma, Trench-Flux, Iron King, and Shattuck Denn properties. The chief silver-producing districts were the Warren (Bisbee), Verde (Jerome), Pioneer (Superior), Ajo, Harshaw, and Big Bug; 57 percent of the State total silver came from the Warren and Verde districts.

Digitized by Google

Copper.—Arizona has been the largest producer of copper in the United States since 1907 except in 1909, when Montana held first place. The output of recoverable copper in Arizona in 1942 was 786,774,000 pounds—an increase of more than 20 percent over 1941 and larger than in any year except 1929, when it was 830,628,411 pounds. The Globe-Miami district, with a production of 188,529,000 net pounds of copper, continued to be the leading copper-producing area in Arizona; it was followed by the Ajo district with 133,293,800 pounds, Copper Mountain (Morenci) with 120,711,000 pounds, Warren (Bisbee) with 106,555,000 pounds, Mineral Creek (Ray) with 100,724,000 pounds, Verde with 87,874,000 pounds, and Pioneer (Superior) with 41,402,800 pounds. These seven districts contributed 99 percent of the State total copper. Copper ore and its products yielded 781,457,631 pounds of copper, as follows: 26,703,329 tons of copper ore treated by concentration yielded 63 percent; 1,954,374 tons of copper ore shipped crude to smelters, 21 percent; and 4,199,268 tons of copper ore leached and 26,781 tons of cement copper (from mine-water precipitates and underground leaching operations), 16 percent. The New Cornelia property continued to be the largest copper producer in Arizona; it was followed in order by the Morenci branch of the Phelps Dodge Corporation, Inspiration, Ray (Nevada Consolidated Copper Corporation), Copper Queen, United Verde, Miami, and Magma properties.

Lead and zinc.—The output of recoverable lead in Arizona in 1942 was 29,544,000 pounds—a decrease of more than 5 percent from the record output of 1941; the output of recoverable zinc was 37,044,000 pounds—the largest in any year in the history of the State and an increase of 12 percent over the record output of 1941. About 47 percent of the State total lead and 36 percent of the zinc came from Santa Cruz County, 13 percent of the lead and 24 percent of the zinc from Pinal County, and 11 percent of the lead and 12 percent of the zinc from Mohave County; most of the remainder of the lead and zinc came from Cochise and Yavapai Counties. About 75 percent of the total lead and more than 72 percent of the total zinc came from zinc-lead ore; nearly all the rest of the lead came from lead ore, siliceous ores, zinc ore, and copper ore; and nearly all the rest of the zinc came from zinc ore. The Trench-Flux group of the American Smelting & Refining Co. near Patagonia in Santa Cruz County was by far the largest producer of lead in the State and the largest producer of zinc; other large producers of lead were the Mammoth-St. Anthony Limited property at Tiger, Tennessee mine at Chloride, Iron King mine at Humboldt, Shattuck Denn mine at Bisbee, and Duquesne property near Patagonia; and other large producers of zinc were the Magma, Iron King, Duquesne, Tennessee, Shattuck Denn, Davenport and Mammoth-St. Anthony Limited properties.

Santa Cruz	1								1	
Yavapai	589	55			35	5	1,916	217	2,540	277
Yuma	213	114							213	114
	885	176			35	5	1,916	217	2,836	398
Total, 1941	976	125	77	5	824	717	10,054	1,358	11,931	2,205

[1] Includes placer sands treated by dry concentration plants.
[2] A floating washing plant supplied with gravel by a dragline excavator is called a "dragline dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."

MINING INDUSTRY

In spite of a serious labor shortage during the summer months in the large copper-producing and zinc-lead districts in Arizona, more ore was mined in 1942 than in any year in the history of the State. The total output (33,920,731 tons) exceeded the peak year 1929 by 8,059,959 tons. The output of copper ore was 32,856,971 tons—a 36-percent gain over 1941; zinc-lead ore, 265,780 tons—a 2-percent gain; lead ore, 25,898 tons—a 41-percent gain; and zinc ore and zinc-copper ore, 113,667 tons—a 37-percent gain. Most of the gold mines in Arizona shut down before July 1, and the output of siliceous ores (chiefly gold ore) was 657,942 tons—a 33-percent loss from 1941. A total of 32,717,333 tons (96 percent of the State total ore output) was copper ore mined in the Globe-Miami, Ajo, Copper Mountain (Morenci), Mineral Creek (Ray), Verde (Jerome), Warren (Bisbee), and Pioneer (Superior) districts; most of the zinc-lead ore was mined in the Big Bug, Harshaw, Wallapai (Chloride), Patagonia, Old Hat (Oracle), and Warren (Bisbee) districts. Placer mining declined considerably, owing to exhaustion of commercial dredging ground.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Arizona in 1942, with content in terms of recovered metals

Source	Mines producing	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Dry and siliceous gold ore	216	498,879	83,586	123,520	323,807	2,290,607	----------
Dry and siliceous gold-silver ore	28	124,668	9,691	379,480	693,839	56,071	----------
Dry and siliceous silver ore	36	34,395	1,033	422,306	27,840	46,967	----------
	[1] 278	657,942	94,310	925,306	1,045,486	2,393,645	----------
Copper ore	125	32,856,971	144,764	4,993,551	[2] 781,457,631	318,900	----------
Lead ore	113	25,898	2,174	101,469	85,258	4,251,345	----------
Lead-copper ore	9	473	15	2,397	18,733	34,966	----------
Zinc ore	4	106,400	1,152	198,954	2,128,230	478,000	9,503,100
Zinc-copper ore	2	7,267	10	6,377	356,300	43,640	679,060
Zinc-lead ore	18	265,780	8,390	836,015	1,682,362	22,023,504	26,861,840
Total, lode mines	[1] 515	33,920,731	250,815	7,064,069	[2] 786,774,000	29,544,000	37,044,000
Total, placers	163	----------	2,836	398	----------	----------	----------
	678	33,920,731	253,651	7,064,467	[2] 786,774,000	29,544,000	37,044,000
Total, 1941	989	25,491,794	315,392	7,498,260	[3] 652,634,000	31,276,000	32,986,000

[1] A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.
[2] Includes 129,292,755 pounds recovered from ore leached and mine-water precipitates.
[3] Includes 118,450,902 pounds recovered from ore leached and mine-water precipitates.

METALLURGIC INDUSTRY

Of the 33,920,731 tons of ore produced in 1942 in Arizona, 27,102,358 tons (80 percent) were treated at concentration plants, 4,199,268 tons (12 percent) at a leaching plant, 543,681 tons (2 percent) at amalgamation, cyanidation, and cyanidation-concentration mills, and 2,075,424 tons (6 percent) were shipped crude to smelters.

Gold ore treated at amalgamation mills decreased from 7,517 tons in 1941 to 765 tons in 1942 and siliceous material treated at cyanidation and cyanidation-concentration plants from 826,393 to 542,916 tons; 15 straight cyanidation plants treated 337,350 tons of material in 1942. The most important plants were those at the Goldroad, Gold Standard, Producers Mines, Inc., Congress, Octave, Mammoth-St. Anthony Limited, Alvarado, Yarnell, Vulture, Vivian, and Iron King properties. Nine companies reported cyaniding 386,332 tons of siliceous material and using 51,400 pounds of sodium cyanide, 666,265 pounds of Aero Brand calcium cyanide, 56,248 pounds of zinc dust, 2,000,000 pounds of lime, 1,277 pounds of Aerosol, and 8,800 pounds of caustic soda.

Ore treated at concentration plants in 1942 comprised chiefly 26,703,329 tons of copper ore, 265,505 tons of zinc-lead ore, 105,971 tons of zinc ore, and 12,121 tons of lead ore. Copper ore from the Miami property (5,922,250 tons) was treated by a combination of leaching and concentration, and copper ore from the Inspiration mine was treated by straight leaching and by leaching and concentration. The large copper-concentration plants at Ajo, Clarkdale, Hayden, Miami, Morenci, and Superior were operated at capacity in 1942, as well as the copper-leaching plants at Inspiration and Miami and the copper smelters at Clarkdale, Douglas, Hayden, Miami, Morenci, and Superior. The rated capacity of charge of the six copper smelters was as follows: Clarkdale 1,400,000 tons per year, Douglas 1,600,000,

Digitized by Google

Hayden 360,000, Miami 360,000, Morenci 450,000, and Superior (Magma) 210,000. In 1942 these plants treated copper material chiefly from one property, with the exception of the Douglas plant, which treated material from various properties in Arizona, New Mexico, and Mexico. The new 25,000-ton concentrator at the Morenci branch of the Phelps Dodge Corporation started running in January, and the new 1,200-ton-per-day copper smelter at Morenci began operating in April. The 20-ton smelter at Tiger is the only lead smelter in Arizona, and it operated exclusively on concentrates from the mill of Mammoth-St. Anthony Limited.

The following tables give details of the treatment of all ores produced in Arizona in 1942.

Mine production of metals in Arizona in 1942, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore amalgamated	765	327	146			
Ore, old tailings, and current tailings cyanided	539,154	45,713	103,800			
Concentrates smelted	1,322,817	105,078	2,668,316	495,590,461	25,760,110	36,734,500
Ore smelted	2,075,424	99,697	4,291,807	161,800,784	3,783,890	309,500
Copper precipitates smelted	26,781			[1] 41,734,764		
Copper ore leached	[2] 4,199,268			87,557,991		
Placer		2,836	398			
Total, 1941		253,651	7,064,467	786,774,000	29,544,000	37,044,000
		315,392	7,498,260	652,634,000	31,276,000	32,986,000

[1] Distributed as follows: Cochise County, 1,067,000 pounds; Gila County, 11,441,500 pounds; Greenlee County, 13,750,000 pounds; Pinal County, 14,749,964 pounds; Santa Cruz County, 1,600 pounds; and Yavapai County, 724,700 pounds.
[2] Treated by straight leaching at 1 plant in Gila County.

Mine production of metals from amalgamation and cyanidation mills (with or without concentration equipment) in Arizona in 1942, by types of mills and by counties, in terms of recovered metals

AMALGAMATION MILLS

Comment on districts with small production has been omitted owing to lack of space.

COCHISE COUNTY

California district (Hilltop).—Nearly all the output in the California district in 1942 was crude lead ore (62 tons) from the Blue Mountain and Silver Hill properties and crude silver ore (59 tons) from the Paradise No. 1 claim.

Cochise district.—Lessees operated the Republic mine near Dragoon in 1942 and shipped 925 tons of copper ore to various smelters in Arizona and 6,300 tons of zinc-copper ore to custom flotation mills in Arizona and New Mexico. The rest of the district output was 112 tons of zinc-lead ore from the Lewis property and 58 tons of copper ore from the Peacock mine.

Dos Cabezas and Tevis district.—The output of the Dos Cabezas and Tevis district in 1942 was principally gold ore (500 tons) from the Dives mine treated in a concentration mill.

Golden Rule (Dragoon) district.—Lessees operated the Golden Rule mine in 1942 and produced 78 tons of silver-lead-gold ore.

Hartford (Huachuca Mountains) district.—Virtually all the output in the Hartford district in 1942 was crude silver-lead ore (73 tons) from the Armistice group near Hereford.

Swisshelm district (Elfrida).—Of the total ore (2,283 tons) produced in the Swisshelm district in 1942, 2,239 tons were crude silver-lead ore from the Scribner mine; the remainder was principally high-grade silver ore from the Silver Leaf claim.

Tombstone district.—The Tombstone Development Co. operated its mine continuously in 1942, shipped 1,130 tons of gold-silver ore and 564 tons of silver-lead ore to the smelter at El Paso, Tex., and treated 250 tons of old tailings (gold-silver) by cyanidation. At the end of the year the company had to abandon its gold-silver-lead operations, owing to Government restriction, but started opening up manganese areas for production. The rest of the district output was mainly crude silver-lead ore (1,568 tons) from the Tombstone Extension mine operated by lessees.

Turquoise district (Courtland, Pearce, Gleeson).—J. P. Giacoma operated the Defiance mine near Gleeson in 1942 and shipped 526 tons of silver-lead ore to the smelter at El Paso, Tex., and 220 tons of carbonate zinc-lead ore to an eastern zinc smelter. The remainder of the district output was largely crude lead ore (139 tons) from the Mystery and Cyclone properties and gold-silver ore (82 tons) from the Commonwealth mine.

Warren district (Bisbee, Warren).—The principal output in the Warren district in 1942 was, as usual, copper ore from the Copper Queen branch of the Phelps Dodge Corporation; 1,111,762 tons of ore were shipped direct to the copper smelters at Douglas and Clarkdale, Ariz. The company also shipped 466 tons of gold-silver fluxing ore, 194 tons of zinc-lead ore, and 1,018 tons of copper precipitates.

According to the company-printed annual report for 1942, development and exploration during the year encountered no new large ore bodies. However, the exploration and development can be considered satisfactory, especially at the Cole and Junction mines. In November, at the request of the War Department and the War Production Board, an agreement was negotiated with Metals Reserve

Digitized by Google

Company which provides for mining marginal ores from certain areas of the Copper Queen Limestone property that are not economic at a 12-cent copper price. Metals Reserve Company pays the cost of this operation plus a small operating profit and receives the copper produced. These ores are shipped to the United Verde smelter at Clarkdale, as there is no furnace capacity for them at the Copper Queen smelter at Douglas.

The Shattuck Denn Mining Corporation operated its Denn mine and 150-ton flotation mill at Bisbee continuously; it shipped 77,857 tons of copper ore to the smelter at El Paso, Tex., and treated 14,876 tons of zinc-lead ore in the mill. This mill also treated several thousand tons of custom ore. The rest of the district output was 5,021 tons of crude ore, mainly copper ore, from the Shattuck mine operated by lessees.

COCONINO COUNTY

Jacob Canyon and Warm Springs district.—Lessees operated the Mackin-Kennedy-Ryan group near Jacob Lake in 1942 and shipped 1,116 tons of carbonate ore to a smelter in Utah. Other producers of similar ore were the Kaibab and Petoskey properties.

Navajo Reservation district.—About 125 tons of carbonate copper ore were produced in 1942 from the Mardun mine east of Cameron.

GILA COUNTY

Banner and Dripping Springs district.—The principal output in the Banner and Dripping Springs district in 1942 was copper ore (39,837 tons) from the Christmas mine shipped direct to a smelter and zinc-lead ore (4,043 tons) and lead ore (620 tons) from the "79" mine. The zinc-lead ore from the "79" mine was shipped to the Denn mill at Bisbee for treatment.

Globe-Miami district.—The Globe-Miami district, with a production of 188,529,000 net pounds of copper in 1942 (164,837,300 net pounds in 1941), remained the chief copper-producing area in Arizona. The Inspiration property, with a yield of 104,320,491 net pounds of copper, was again the largest producer of copper in the district and ranked third in the State. The Inspiration Consolidated Copper Co. reported that 4,199,268 tons of copper ore from which the slimes had been removed were treated by ferric sulfate leaching; the slimes (333,784 tons) removed from the ore and 503,648 tons of additional crude copper ore were treated at the concentrator to recover the sulfide copper, and the tailings were treated with sulfuric acid to dissolve the oxide copper.

According to the printed annual report of the company for 1942, the mine, main leaching plant, slimes leaching plant, and that part of the concentrator treating slimes for the recovery of their sulfide copper content operated continuously throughout the year. The original flotation concentrator was altered during the year to provide treatment facilities for 4,000 tons of mixed crude ore a day by the leach-float process. This process involves sulfuric acid leaching of the oxide copper content of the ore, precipitating the dissolved copper as cement copper and floating it, with the sulfide copper content of the ore, as a concentrate. Treatment of crude ore by this process commenced July 13, 1942, and continued throughout the remainder of the year. Construction of a 100-ton daily capacity sulfuric acid plant was com-

Digitized by Google

pleted in September and put in operation. An acute shortage of available labor continued throughout the year. A number of women were employed in several sections of the plant, and their work has proved satisfactory. In October the Army furloughed 100 soldiers for underground work which, in part, alleviated the labor shortage.

The Miami Copper Co. operated its mine, 18,000-ton concentrator, and 3,000-ton leaching plant continuously; 5,922,250 tons of copper ore were treated by the leach-float process (as at Inspiration). In addition, 3,778 tons of copper precipitates were produced from leaching in place, and 426 tons of molybdenum concentrate were recovered from the copper ore.

According to the company printed annual report for 1942, operations were continuous throughout the year in both the mixed and sulfide ore bodies and in leaching copper from broken gob overlying worked-out portions of the ore body. The tonnage of ore mined was the largest (except 1930) in the 32-year life of the property, and copper production was greater than in any previous year. A shortage of labor was considerably alleviated toward the end of the year through the furloughing of essential mine labor from the Army and through the assistance of the United States Employment Service. In spite of a labor shortage, copper production was maintained at a maximum rate throughout the year at the expense of mine development, which fell behind to such an extent that a reduction in copper production is expected until such time as the necessary manpower becomes available to bring mine development back to normal, and every effort is being made in this direction. Exhaustion of the mixed-ore body, estimated to take place in the fall of 1942, has not yet occurred and it will probably continue in production through the first quarter of 1943.

The rest of the district output was largely crude copper ore (15,152 tons), principally from the Carlota mine near Miami.

The Castle Dome Copper Co., Inc., a wholly owned subsidiary of the Miami Copper Co., started in January 1942 to develop the Castle Dome ore body near Miami and to erect a treatment plant. It is expected that the mill will be completed and ore developed during the summer of 1943. The mill is straight flotation; mining is conducted by the open-cut method.

Green Valley district (*Payson*).—About 100 tons of gold ore were shipped in 1942 from the Summit mine dump near Payson and 5 tons of copper ore from the Copper King claim.

Pioneer (*Pinal Mountains*) *district*.—Nearly all (58 tons) the output in the Pioneer district in 1942 was silver ore from the Bob Tail, Pioneer, and Vindicator properties south of Globe.

GRAHAM COUNTY

The output of Graham County in 1942 was mainly 929 tons of crude lead ore from the Aravaipa mine near Klondyke and 311 tons of similar ore from the Ten Strike claim, both in the Aravaipa district.

GREENLEE COUNTY

Ash Peak district (*Duncan*).—The output of the Ash Peak district in 1942 was 20,756 tons of silver ore shipped direct to a smelter. Leasing operations at the Ash Peak mine produced 19,041 tons, and the remainder (1,715 tons) came from the Hardy mine.

556250—43——17

Digitized by Google

Copper Mountain district (Morenci).—The most important output in the Copper Mountain district continued in 1942 to be copper ore and copper precipitates from the Morenci branch of the Phelps Dodge Corporation; the output comprised 7,640,890 tons of copper ore treated by concentration, 53,006 tons of copper ore shipped direct to the new Morenci smelter, and 8,986 tons of copper precipitates smelted. The rest of the district output was 837 tons of gold ore shipped to a smelter from the Climax (Emma Gomez) and Gold Belt properties and 116 tons of copper ore from the Keating mine.

According to the annual report of the Phelps Dodge Corporation for 1942, regular production from the Morenci open pit commenced at the end of January, and the new 25,000-ton concentrator received its first ore January 30. The initial charging of the first smelter furnace started in April, and full capacity of all operations occurred in the following 6-week period. Until July a portion of the concentrate production was shipped to the Copper Queen smelter at Douglas. Production of copper from leaching operations was increased in 1942 by the output from the new Metcalf precipitation plant, which treats copper-bearing waters from the old Coronado mine. At the close of the year, 15 mining benches were operated at the open pit. In March 1942 the corporation concluded negotiations with the Defense Plant Corporation for enlargement of operations at the Morenci open pit and reduction works and also of the capacity of the El Paso copper refinery. It is estimated that construction work on the program will be completed about August 1, 1943, and that the new facilities will be operating at capacity some time during the last quarter of the year.

MARICOPA COUNTY

Cave Creek and Camp Creek district.—Virtually all the output in the Cave Creek and Camp Creek district in 1942 was gold ore; most of it (210 tons) was from the Maricopa mine, treated by amalgamation.

New River (Moors) district.—The Orizaba Mining Co. operated the Orizaba mine in 1942 and shipped 1,898 tons of copper ore to a smelter. A little gold ore was shipped from the Leland, Minnie Lee, and Moore properties.

Osborn district.—A total of 1,624 tons of ore was produced from two mines in the Osborn district in 1942; the output comprised 1,155 tons of crude lead ore from the Moon Anchor mine and 434 tons of lead ore and 35 tons of lead-copper ore from the Belmont-McNeil mine.

Salt River Mountains district.—The Park View Mining Co. operated the Delta mine near Phoenix 4 months in 1942; about 450 tons of gold ore were treated in a flotation mill, and 211 tons of similar ore were shipped to a smelter. Gold ore was produced also from the North Delta claim.

Sunflower (Mazatzal) district.—A lessee operated the Little Daisy mine 3 months in 1942 and shipped 52 tons of gold ore to a smelter.

Vulture district.—Gold ore (34,143 tons) from the Vulture mine was again the most important output in the Vulture district in 1942. The East Vulture Mining Co. operated the mine and its 300-ton

Digitized by Google

cyanide and concentration mill continuously until December 15. The rest of the district output was mainly lead ore (926 tons) from the Montezuma mine and silver ore (269 tons) from the Newsboy (Pitt) mine.

Wickenburg district.—About 1,000 tons of old tailings (gold) from a dump near Wickenburg were treated in 1942 by cyanidation.

MOHAVE COUNTY

Bentley (Grand Wash) district.—Carbonate ore (36 tons) averaging 26 percent copper to the ton was shipped in 1942 from the Grand Gulch mine.

Cedar Valley district.—Molybdenum Corporation of America operated the Boriana mine near Yucca throughout 1942 and treated 10,000 tons of tungsten-copper ore by gravity concentration and flotation; copper concentrates were shipped to a smelter in Arizona and tungsten concentrates to an eastern market.

Cottonwood district.—Lessees operated the Copper Giant mine near Hackberry in 1942 and shipped 2,030 tons of gold-copper ore to a smelter.

Gold Basin district.—Nearly all the output of the Gold Basin district in 1942 was gold ore and old tailings treated in a custom cyanide mill; the chief producers were the O. K., Excelsior, and Golden Link properties. Placer gold (19 fine ounces) was recovered by various operators working at the Gold Basin Placers.

Indian Secret (White Hills) district.—A 40-ton cyanide leaching plant was built in 1942 at the White Hills property, and during the year 250 tons of silver ore were treated.

Maynard and McConnico district.—Mining and milling at the Bimetal open-pit mine near Kingman ceased in January 1942; before closing about 100 tons of gold ore were treated by flotation. The rest of the district output was 25 tons of gold ore from the Columbus-Lead Carbonate group.

Minnesota district.—The output of ore in the Minnesota district totaled 171 tons in 1942; most of it was gold-silver ore cyanided from the Horn Silver mine and gold ore cyanided from the Blue Rock mine.

Music Mountain district.—Lessees operated the Mohawk mine near Valentine in 1942 and treated 153 tons of gold ore by amalgamation and concentration. The remainder of the district output was principally rich gold ore (74 tons) from the Roosevelt mine, shipped to a smelter.

Owens (McCracken and Potts Mountain) district.—The Cleopatra mine was operated nearly all year by Strong & Harris, who shipped 2,798 tons of gold-copper ore to the smelter at Clarkdale. The rest of the district output was mainly small lots of gold ore and copper-gold ore produced from various claims and sold to the Wickenburg Ore Market.

San Francisco (Oatman, Goldroad, Katherine, Vivian) district.—Production of gold in the San Francisco district was 28,570 fine ounces in 1942 compared with 42,098 fine ounces in 1941. More than 74 percent of the output came from the Goldroad mine at Goldroad and most of the remainder from the Tyro mine at Katherine. The United

Digitized by Google

States Smelting, Refining & Mining Co. operated the Goldroad mine continuously until September 20 and treated 99,298 tons of gold ore in the company 300-ton cyanide plant. The Tyro mine and 300-ton cyanide mill of the Gold Standard Mines Corporation were operated throughout the year; the company treated 77,089 tons of low-grade gold ore from the Tyro mine and 510 tons of custom ore. The Vivian Mining Co. operated its 100-ton custom cyanide mill until March 1; about 1,450 tons of gold ore were treated, principally from the Vivian-Lelande-Mitchell and Pioneer properties. Other gold producers included the Big Jim, Burt, Gold Dust, King of Secret Pass, Minnie, Philadelphia, Ruth-Rattan, and Telluride properties.

Wallapai district (Cerbat, Chloride, Mineral Park, Stockton Hill).—Approximately 70,500 tons of ore were produced in the Wallapai district in 1942; nearly 57 percent of it was zinc-lead ore from the Tennessee mine, 26 percent was zinc ore from the Middle Golconda-Oro Plata group, and the remainder was largely gold ore from various properties. The Tennessee mine at Chloride was operated throughout the year by the Tennessee-Schuylkill Corporation; 40,055 tons of zinc-lead ore were treated in the company 150-ton flotation mill. The Davenport Mining & Reduction Co. operated the Middle Golconda-Oro Plata group continuously until September 11, when operations ceased, owing to a shortage of available labor. During the year 18,636 tons of zinc ore were treated in the company 100-ton flotation mill. About 2,800 tons of gold ore from the Golden Gem mine were concentrated in a mill on the property, and 1,026 tons of similar ore from the mine dump were cyanided in a custom mill. Silver ore (1,000 tons) from the C. O. D. mine was concentrated, a total of 1,076 tons of gold-silver ore from the Juno and Nighthawk mines was cyanided, and 446 tons of zinc-lead ore from the Minnesota-Connor property were concentrated. Other producers of gold ore included the Emerson, Flores, Hidden Treasure, O'Brien, Rambler, Red Seal, Rico, and Summit properties.

Weaver (Mocking Bird, Pilgrim, Portland) district.—Output of ore in the Weaver district declined from 18,858 tons in 1941 to 3,861 tons in 1942. The principal output in 1942 was 3,733 tons of gold ore from the Golden Door mine treated in the custom cyanide mill of Producers Mines, Inc. This company operated its 300-ton cyanide mill continuously on custom ore until May 15, when it closed permanently.

PIMA COUNTY

Ajo district.—The New Cornelia open-pit mine, the only producer in the Ajo district in 1942, was operated at capacity throughout the year by the Phelps Dodge Corporation; 8,324,033 tons of copper ore were treated by flotation, and 704 tons of crude copper ore were shipped direct to a smelter. The capacity of the concentrator was increased from 22,500 to 25,000 tons of ore a day, and the mine remained the largest producer of copper in Arizona. According to the annual report of the corporation for 1942, necessary work was done in the open pit with a view to meeting the increased production problem; double tracking was done on several of the waste dumps. At the concentrator certain structural changes in milling equipment, designed to increase production still further, were completed and satisfactory results obtained.

Digitized by Google

Amole district.—Virtually all the output of the Amole district in 1942 was crude lead ore (607 tons) from the Old Yuma mine near Tucson; the property was worked part of the year by the Tucson Ore Milling Co.

Arivaca district.—Gold ore (70 tons) shipped to a smelter from the Backbone and Oreona mines was the chief output in the Arivaca district in 1942.

Baboquivari district.—All the output (1,700 tons) in the Baboquivari district in 1942 was gold ore from the Allison mine, operated by the Gold Bar Mining Co.; both the mine and 50-ton cyanide mill shut down March 1.

Cababi (Comobabi) district.—About 85 tons of ore were produced in the Cababi district in 1942; most of it was copper ore from the Serenake mine, gold ore from the Grand Central mine, and lead ore from the Stepp claim.

Cerro Colorado district.—Silver ore (62 tons) and lead-copper ore (5 tons) were produced in 1942 from the Mary "G" mine.

Empire district.—E. P. Hilton operated the State of Maine mine in 1942 and shipped 145 tons of carbonate lead ore to El Paso, Tex., and 429 tons of carbonate zinc ore to Coffeyville, Kans.

Helvetia (Rosemont) district.—The Helvetia Mining & Milling Co. was organized in 1942 to operate the Copper World (Leader) mine; during the year 2,000 tons of copper ore were treated in a concentration mill, and 1,599 tons of similar ore were shipped direct to a smelter. Copper ore (855 tons) was shipped also from the Rosemont mine by a lessee and lead-copper ore (11 tons) from the Mohawk claim.

Old Hat district (Oracle).—Three mines in the Old Hat district in Pima County produced 12,149 tons of copper ore in 1942; most (12,000 tons) of it was treated in a 100-ton flotation mill and came from the Daily and Geeseman groups operated by Control Mines, Inc.

Pima (Sierritas, Papago, Twin Buttes) district.—Nearly all the output in the Pima district in 1942 was crude silver-lead ore (96 tons) from the Esperanza, High Hill, and Two Friends properties and crude copper ore (65 tons) from the Armargoza, Copper Glance, and King properties.

Quijotoa district.—Copper ore (35 tons) was produced in 1942 from the Highland and Coplen mines and lead ore (30 tons) from the Tres Metals claim.

Roskruge and Waterman (Silver Hill) district.—Leasing operations at the Silver Hill mine in 1942 produced 145 tons of silver-lead ore and 44 tons of copper ore.

Silver Bell district.—George T. Harford operated the Arizona Copper & Mint property in 1942 and shipped 100 tons of silver-lead-copper ore to a smelter.

PINAL COUNTY

Bunker Hill district (Copper Creek).—The Bunker Hill and Magma Chief properties were operated in 1942; 370 tons of lead-copper ore from the Bunker Hill mine were concentrated, and 210 tons of copper ore from the Magma Chief mine were shipped direct to a smelter.

Casa Grande district.—The output of the Casa Grande district in 1942 comprised 253 tons of silver ore from the Silver Reef mine; 89 tons of gold ore from the Old Jonah and Turning Point mines, 57 tons of copper ore from the Slate Mountain and Andrade properties, and 44 tons of lead ore from the Sheridan Range and Sunrise properties.

Digitized by Google

Mineral Creek district (Ray).—Nevada Consolidated Copper Corporation (subsidiary of Kennecott Copper Corporation) operated its mine at Ray and 12,000-ton concentrator at Hayden at capacity throughout the year; 2,967,941 tons of copper ore were treated by flotation, and 1,327 tons of crude copper ore and 8,371 tons of copper precipitates were shipped to the smelter at Hayden. The rest of the district output was 276 tons of copper ore from the Copper Butte mine.

Mineral Hill district.—The principal output in the Mineral Hill district in 1942 was gold ore (1,079 tons) shipped to a smelter from the Consolidated Gold, Sunset, and Wedge properties.

Old Hat district (Oracle).—In June 1942 the Mammoth-St. Anthony Limited installed additional flotation equipment in its 550-ton mill to treat sulfide zinc-lead ore; heretofore, the mill had treated only oxidized gold-silver-lead-molybdenum-vanadium ore. During the year 147,293 tons of such ore were treated by gravity concentration, followed by flotation, the flotation tailings were treated by cyanidation, and 15,700 tons of zinc-lead ore were treated by straight flotation. The oxide lead concentrates were smelted in the company 20-ton lead furnace, and the sulfide lead concentrates were shipped to El Paso, Tex. Gold precipitates, as well as molybdenum and vanadium products, were shipped East and zinc concentrates to Amarillo, Tex. The rest of the district output was mainly 45 tons of crude lead ore from the Mammoth Tiger Extension mine.

Pioneer district (Superior).—Copper ore and zinc-copper ore from the Magma mine continued in 1942 to be the principal output in the Pioneer district. The Magma Copper Co. operated its mine, 850-ton concentrator, and 450-ton copper smelter throughout the year, except for brief shut-downs to allow for repairs. The company reported that 281,283 tons of copper ore and 87,105 tons of zinc-copper ore were treated in the concentrator, and 77,728 tons of copper ore were sent direct to the smelter. The zinc concentrates (8,748 tons) were shipped to Amarillo, Tex.

According to the company printed annual report for 1942, the average net cost of producing copper after deduction of gold, silver, and zinc concentrate values was 9.66 cents a pound compared with 7.90 cents a pound in 1941. Development in 1942 comprised 8,647 feet of drifting, 4,985 feet of raising, 749 feet of sinking, and 4,073 feet of cross-cutting; the shaft is now down to the 4,908 level. During the summer months production of ore dropped because of four retarding factors—excessive heat throughout the lower levels of the mine, loss of many skilled employees to other higher-paid war industries and to the armed forces, inexperience and inefficiency of many of the labor replacements, and inability to obtain a sufficient number of labor replacements of any kind from August to October. In October the company obtained some experienced miners released from the Army and some gold miners from the Colorado gold mines closed by Government regulations. Commencing with October production increased; however, it took approximately 10 percent more men underground to attain this increase. The tonnage of zinc-copper ore mined in 1942 was greater than in any previous year, but during December 1942 to June 1943 the zinc content of the ore has diminished greatly; the gold and silver content of the copper ore on the lower levels of the mine has also decreased seriously.

Digitized by Google

The rest of the district output was mainly crude silver ore (8,096 tons) from the Reymert mine, crude gold ore (759 tons) from the Lake Superior & Arizona property, and silver ore (601 tons) from the Belmont and Queen Creek properties.

SANTA CRUZ COUNTY

Harshaw district.—In 1942, as in 1941, the principal output in the Harshaw district was zinc-lead-silver ore from the Trench and Flux groups operated by the American Smelting & Refining Co. The company 200-ton flotation mill ran continuously and treated 76,855 tons of zinc-lead-silver ore; it was the largest producer of lead and zinc in Arizona in 1942. The rest of the district output was crude silver-lead ore (297 tons) from the American, Hardshell, and World's Fair properties.

Oro Blanco district (Ruby).—About 1,800 tons of ore were produced in the Oro Blanco district in 1942; most of it was crude silver ore (1,133 tons) from the Brick mines, gold ore (269 tons) from the Noon and Oro Blanco properties, and gold-silver ore (237 tons) from the Old Soldier and Tres Amigos group.

Patagonia (Duquesne) district.—In 1942 zinc-lead-copper ore from the Duquesne mine, operated by the Callahan Zinc-Lead Co., was the most important output in the Patagonia district. The company 125-ton flotation mill ran continuously and treated 31,136 tons of zinc-lead-copper ore (including 967 tons of custom ore); copper concentrates (1,432 tons) and lead-copper concentrates (1,016 tons) were shipped to El Paso, Tex., and zinc concentrates (4,011 tons) to Amarillo, Tex. The remainder of the district output was chiefly zinc-lead-copper ore (967 tons) from the Pride of the West mine treated in the Duquesne mill.

Tyndall district.—The output of the Tyndall district in 1942 was principally crude lead ore (207 tons) and zinc-lead milling ore (337 tons) from the Jefferson mine, and silver-lead ore (238 tons) from the Alto and Eureka properties.

Wrightson district.—Lead-copper ore (30 tons) was produced in 1942 from the Armada mine and lead ore (7 tons) from the Lead King claim.

YAVAPAI COUNTY

Agua Fria district.—All the output of the Agua Fria district in 1942 was crude copper ore (450 tons) from the Burzog (Old Minor) and Stoddard properties east of Mayer.

Big Bug district.—The principal output in the Big Bug district in 1942 was, as in 1941, zinc-lead ore and gold-silver ore from the Iron King mine at Humboldt. The mine was operated continuously—the first 6 months of 1942 by the Iron King Mining Co. and the last 6 months by the Shattuck Denn Mining Corporation, which purchased the property July 1; 76,757 tons of zinc-lead ore were treated in the company 240-ton flotation mill, 65,018 tons of current flotation tailings (gold-silver) were treated by cyanidation, and 12,393 tons of crude gold-silver ore were shipped to a smelter. The remainder of the district lode output was largely old tailings (1,298 tons) containing gold, silver, and copper shipped from the Humboldt tailing dump. More than one-half of the State placer gold production in 1942 was

Digitized by Google

recovered from properties in this district; the chief producer was the Arical Mines, Inc., operating a dragline floating dredge at the Black Walnut, Farnum, and Shanks properties.

Black Canyon district.—The Golden Turkey Mining Co., Inc., a large producer of gold from 1933 to 1941, inclusive, closed its mine and 200-ton mill near Cordes in January 1942; the mill treated 1,140 tons of gold ore in 1942. The rest of the district output was mainly gold-silver ore (33 tons) from the Hidden Treasure mine and silver ore (30 tons) from the Thunderbolt mine.

Black Hills district.—The output of the Black Hills district in 1942 was 245 tons of gold ore from the Ambassador and D. & M. properties near Dewey and 32 tons of copper ore from the Yaeger mine.

Black Rock district.—The Super X (Atos) mine near Wickenburg was worked until May 31, 1942, and 900 tons of gold ore were treated by cyanide leaching. The remainder of the district output was chiefly crude gold ore (376 tons) from the George Washington, Gold Crown, and Golden Gate properties.

Blue Tank district.—Leasing operations at the Franklin D. mine produced 43 tons of gold ore in 1942, and 9 fine ounces of placer gold were recovered from claims along the Hassayampa River.

Bullard (Pierce) district.—Virtually all the output in the Bullard district in 1942 was crude gold-copper ore (289 tons) from the Bullard and Metz properties near Aguila.

Castle Creek district.—Small lots of various classes of ore were produced from claims in the Castle Creek district in 1942 and sold to the Wickenburg Ore Market.

Cherry Creek district.—Eight mines in the Cherry Creek district produced a total of 258 tons of crude gold ore in 1942; the chief producers were the Gray Eagle, Bugler, Sitting Bull, Black Hawk, and Volcano properties.

Copper Basin district.—The Commercial mine near Skull Valley was worked by a lessee in 1942, and 9,167 tons of copper ore were shipped to a smelter. The rest of the district lode output was mainly sulfide zinc ore (230 tons) from the Boston-Arizona mine and high-grade gold ore (15 tons) from the Stanley A. claim. About 15 fine ounces of placer gold were recovered from various claims along Copper Basin Wash.

Eureka district.—Copper ore from the Bagdad mine, operated by the Bagdad Copper Corporation, was the principal output in the Eureka district in 1942; 56,392 tons of ore were treated in the company 250-ton flotation mill. The company also built a new 2,500-ton mill and prepared the mine for greatly increased output in 1943. The Hillside mine—a large producer of gold, silver, lead, and zinc in 1941—was shut down in January 1942; during the month about 3,000 tons of zinc-lead ore were treated by flotation. Later in the year a lessee operated the mine and shipped 200 tons of crude gold-silver ore to a smelter. The remainder of the district output was chiefly gold ore (377 tons) from the April Showers, Big Stick, Bland, Crosby, Homestake, and New Year properties.

Hassayampa (Groom Creek, Hassayampa River, Senator, Prescott) district.—Seventeen lode mines in the Hassayampa district produced 285 tons of ore in 1942; most of it was gold ore (205 tons) shipped direct to a smelter from the Eureka, Golden Summer, Independence,

Digitized by Google

Oro Flame, and Railroad properties. The output of placer gold totaled 546 fine ounces, which was recovered chiefly at the Hobbs property by a dragline floating dredge during the first 2 months of the year.

Kirkland district.—The only output in the Kirkland district in 1942 was 47 tons of gold ore from the Venus mine.

Lynx Creek district.—The output of placer gold in the Lynx Creek district decreased from 4,372 fine ounces in 1941 to 87 fine ounces in 1942; most of the gold in 1942 was recovered by a dry-land dredge in January at the Speck-Lynx Creek property.

Martinez (Congress) district.—The Congress Mining Corporation, a large producer of gold since 1938, closed its 300-ton cyanide mill May 1, 1942. During the first 4 months of the year the mill treated 32,800 tons of gold ore and old tailings from the Congress property. From June 1 to the end of the year lessees worked in the mine and shipped 378 tons of crude gold ore to a smelter. The rest of the district output was mainly 600 tons of gold ore (concentrated) from the Niagara-Congress waste dump.

Peck district.—Virtually all the output in the Peck district in 1942 was crude silver ore (204 tons) shipped to a smelter from the Battle Flat and Swastika mines near Crown King.

Pine Grove district (Crown King).—The most important producer in the Pine Grove district in 1942 was, as in 1941, the Gladiator-War Eagle group operated by the Gladiator Mining Co. During the first 7 months of the year 1,952 tons of crude gold ore were shipped direct to a smelter; in August the company completed the erecting of a 50-ton mill, and during the remainder of the year 2,500 tons of zinc-lead-gold ore were treated by flotation. Lead concentrates containing an average of 6.31 ounces of gold to the ton were shipped to El Paso, Tex., and zinc concentrates to Amarillo, Tex. The rest of the district output was mainly 206 tons of crude gold-lead ore from the Del Pasco mine.

Pocket Creek district.—Sluicing at the Pocket Creek Placer in 1942 recovered 201 fine ounces of gold and 7 fine ounces of silver.

Tiger district.—Six mines in the Tiger district produced 263 tons of ore in 1942; most of it was gold ore (153 tons) from the Fortuna, Pilgrim, and Snowdrift properties and silver ore (100 tons) from the Tiger mine.

Verde district (Jerome).—The principal output in the Verde district in 1942 was, as usual, copper ore from the United Verde mine of the Phelps Dodge Corporation. The mine and 2,100-ton concentrator were operated throughout the year; 563,140 tons of copper ore and old tailings and 413 tons of copper precipitates were shipped direct to the company smelter at Clarkdale, and 649,108 tons of copper ore were treated in the concentrator.

According to the printed annual report of the corporation for 1942 ore production at the United Verde mine was confined to the underground areas. By the end of the year all copper mining areas above the 1,650 level had been abandoned on account of depletion of available ores. The development program for the lower levels was pushed, and the No. 8 shaft sinking was completed to the 4,631 level. An adjustment of the production quota for the United Verde mine under

Digitized by Google

the premium-price plan made it possible to make a moderate increase in copper production by mining certain marginal or low-grade ores during the last quarter of the year.

Lessees continued to work the Iron King-Equator group and shipped 24,477 tons of siliceous gold-silver ore to a smelter. The rest of the district output was chiefly 4,012 tons of crude copper ore from the Dundee-Arizona mine and 1,337 tons of crude gold-silver ore from the Silver Plate property.

Walker district.—The French Sheldon Mines operated the Sheldon property until October 20; about 1,000 tons of gold-silver ore were treated in the 100-ton concentration mill, and 1,036 tons of crude gold ore were shipped to a smelter. The remainder of the district lode output was largely 377 tons of zinc-lead milling ore from the New Strike mine and 341 tons of high-grade gold ore shipped to a smelter from the Champion, Emma, Good Luck, Lost Wonder, and Oro Plata properties. Approximately 20 fine ounces of placer gold were recovered from various claims on Lynx Creek near Walker.

Weaver district (Octave).—The principal output in the Weaver district in 1942 was, as usual, gold ore from the Alvarado, Octave, and Yarnell properties. However, the Octave mine, the largest producer of gold in the district since 1934, was closed in December, the Alvarado in June, and the Yarnell in September. The 80-ton flotation mill at the Octave mine treated 24,188 tons of gold ore, and the flotation tailings (23,718 tons) were cyanided. In addition, 471 tons of crude gold ore were shipped to a smelter. The Alvarado mine and 100-ton mill were worked by the Liberty Hill Gold Mines until June 30; 18,993 tons of gold ore were treated by cyanide leaching. About 26,500 tons of similar ore from the Yarnell mine were treated also by cyanide leaching. The remainder of the district lode output was chiefly gold ore (267 tons) shipped to a smelter from the Monica, May Queen, and Turtle properties. The output (56 fine ounces) of placer gold was recovered from various claims along Weaver Creek and at Rich Hill.

White Picacho district.—Nearly all the output in the White Picacho district in 1942 was silver-lead ore (1,155 tons) shipped to a smelter from the Diamond Joe mine near Wickenburg.

YUMA COUNTY

Castle Dome district.—The Arizona Lead Co. leased the Eliza DeLuce group in 1942 and built a 100-ton concentration mill on the property; from August 13 to the end of the year the mill treated 11,007 tons of silver-lead ore and old tailings. The rest of the district output was mainly 111 fine ounces of placer gold recovered by a Stebbins dry concentrator at the Ocatilla property.

Cienega district.—Leasing operations at the Empire Arizona and Mavis properties near Parker produced 826 tons of crude gold-copper ore in 1942.

Ellsworth district (Salome).—About 640 tons of ore were produced in the Ellsworth district in 1942; most of it was crude gold-copper ore (436 tons) from the Centroid, Critic, Moore, Sheba, and Yuma Copper properties and crude gold ore (100 tons) from the Bunker Hill and Hercules mines.

Digitized by Google

Plomosa district.—Nearly all the lode output in the Plomosa district in 1942 was crude silver ore (984 tons) from the R. & A. mine and crude gold ore (847 tons) and crude gold-copper ore (67 tons) from the Little Butte mine near Bouse. The output of 51 fine ounces of placer gold was recovered chiefly from the Can Do (Erdman), Cave Creek, and Sax properties.

Santa Maria (Planet, Bill Williams) district.—The Swansea Development Co. worked the Swansea mine throughout the year and shipped 293 tons of crude copper ore to a smelter. The property is equipped with a 250-ton flotation mill, and plans were made in December to bring the mine back to capacity production.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN CALIFORNIA

(MINE REPORT)

By CHARLES WHITE MERRILL AND H. M. GAYLORD

SUMMARY OUTLINE

	Page		Page
Summary	261	Mining industry	269
Calculation of value of metal production	262	Ore classification	270
Mine production by counties	267	Metallurgic industry	271
		Review by counties and districts	276

SUMMARY

The 39-percent decline in the total value of California output of gold, silver, copper, lead, and zinc in 1942 compared with 1941 does not nearly picture the disastrous effect of war on the industry. The production rate in December sank below the monthly average for any year since 1848. Gold, silver, and copper output in 1942 was below 1941 levels, but lead and zinc production rose. Higher wages, enlistment of miners in the armed forces, migration of miners to war industries, rising prices of supplies and equipment and difficulties in obtaining them, increased taxes, and the fixed prices for gold and silver (the most important of the five metals in California) were factors accelerating the downward trend, which was already under way in 1941. Although War Production Board Order L–208 popularly was assigned as the cause of the great decline in California's gold industry, a review of the 1941–42 monthly production record does not substantiate this view. The recession was virtually uninterrupted for the 2 years, and the rate of decline in October and November 1942, when the order was taking effect, did not deviate from the general 2-year pattern. (See Gold and Silver chapter of this volume for text of Order L–208.)

Comparing 1942 with 1941, gold decreased 40 percent and silver 33 percent in both quantity and value; copper decreased 73 percent in quantity and 72 percent in value; lead increased 49 percent in quantity and 75 percent in value; and zinc increased 39 percent in quantity and 73 percent in value. Of the total value of the five metals in 1942, gold represented 93 percent, silver 3 percent, lead 2 percent, and copper and zinc 1 percent each.

Despite a 42-percent slump for 1942 in total value of production, Nevada County continued to be the largest contributor to the metal-mining output of California; it supplied 18 percent of the State total value of the five metals, 19 percent of the total gold, and 40 percent of the lode gold. Sacramento County (largely from gold dredging) contributed 14 percent of the total value of the five metals; Yuba County (largely from gold dredging) and Kern County (largely from gold ore

Digitized by Google

and old tailings), 8 percent each; Butte County (largely from placer gravels), 7 percent; Amador County (largely from gold ore) and Inyo County (from gold, lead, tungsten, and zinc ores), 5 percent each; Siskiyou County (largely from placer gravels), 4 percent; and Calaveras County (from gold ore, gravels, and copper ore) and Mariposa County (two-thirds from gold ore and one-third from gravels), 3 percent each. Thus, each of the foregoing 10 of the 36 counties producing the five metals in California in 1942 contributed over 1 million

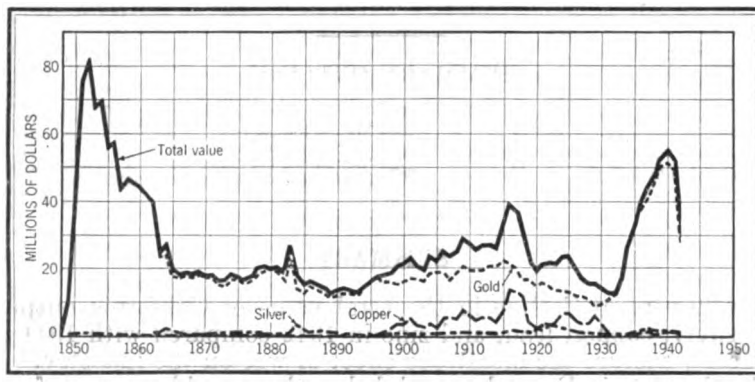

FIGURE 1.—Value of mine production of gold, silver, and copper and total value of gold, silver, copper, lead, and zinc in California, 1848-1942. The value of lead and zinc has exceeded $1,000,000 in only a few years.

dollars worth; together, they supplied over three-fourths of the total for these metals.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

Yardage figures used in measuring material treated in placer operations are "bank measure"; that is, the material is measured in the ground before treatment.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1938–42

Year	Gold [1]	Silver [2]	Copper [3]	Lead [4]	Zinc
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1938	$35.00	[5] $0.646+	$0.098	$0.046	$0.048
1939	35.00	[6] .678+	.104	.047	.052
1940	35.00	[7] .711+	.113	.050	.063
1941	35.00	[7] .711+	.118	.057	.075
1942	35.00	[7] .711+	.121	.067	.093

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.

[2] Treasury buying price for newly mined silver.

[3] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production but excludes value of foreign copper delivered to Metals Reserve Co. for domestic consumption.

[4] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production.

[5] $0.64646464. [6] $0.67878787. [7] $0.71111111.

1848–1942 [1]			[8]	65,005,068	1,410,915,026	[8]

[1] For historic data by years see Minerals Yearbook, Review of 1940, p. 219.
[2] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property worked.
[3] First year for which this method was reported used in California.
[4] Includes all placer operations using suction pump for delivering gravel to floating washing plant, except those producing less than 100 ounces of gold which are included under "Small-scale hand methods."
[5] Includes all placer operations using power excavator and washing plant, both on dry land; when washing plant is movable, outfit is termed "dry-land dredge."
[6] Includes all operations in which hand labor is principal factor in delivering gravel to sluices, long toms, dip boxes, pans, rockers, dry washers, etc.
[7] A mine using more than 1 method of recovery is counted but once in arriving at total for all methods.
[8] Complete data not available.

Gold.—An uninterrupted rise beginning in 1929 culminated in the production of $50,948,485 in gold in 1940, the largest value since 1856. In 1941, however, a reaction set in and gained headway in 1942. Monthly production declined approximately 4 percent a month fairly regularly from January 1941 to May 1942, when the downward trend greatly accelerated and continued at about 16 percent a month to December 1942. Strangely, the period when War Production Board Order L–208 was becoming effective did not mark a substantial change in the trend. Apparently, economic forces were curtailing gold production so rapidly in 1942 that exercise of Federal authority was not needed to accomplish a most drastic curtailment in gold mining in California. Production in December was at an annual rate of 246,612 fine ounces or $8,631,420, which, except for 1929 (when California

Digitized by Google

gold output was valued at $8,526,703), represented the lowest level since 1848.

The 25 leading gold-producing mines in California in 1942, listed in the following table, yielded 60 percent of the total gold output of the State. In 1942, six placers (five connected-bucket dredges and one dragline dredge) and two lode mines (gold ore) displaced two placers (connected-bucket dredges) and six lodes (five gold ore and one copper ore). Of those displaced, none was working at the end of 1942. Of those on the 1942 list, only four were producing at the close of the year.

Twenty-five leading gold-producing mines in California in 1942, in order of output

Rank	Mine	District	County	Rank in 1941	Operator	Source of gold
1	Natomas Co.	Folsom	Sacramento	2	Natomas Co.	Dredge.
2	Yuba Unit	Yuba River	Yuba	4	Yuba Consolidated Gold Fields.	Do.

25	Kister property	Oroville	Butte	43	Gold Hill Dredging Co.	Do.

[1] Corrected figure.

Silver.—Most of the silver output in California in 1942 was more localized than that of the gold; the 10 leading silver-producing mines, listed in the following table, yielded 85 percent of the State total recoverable silver in that year. The list is similar to that of 1941, except for some changes in rank and the displacement of the Starlight mine (consolidated with its neighbor), Walker, and Grigsby mines, which suspended operations in 1941. By December, 6 of the 10 leading silver mines had suspended operations.

Ten leading silver-producing mines in California in 1942, in order of output

Rank	Mine	District	County	Rank in 1941	Operator	Source of silver
1	Cactus Queen	Mojave	Kern	1	Cactus Mines Co	Gold-silver ore.
2	Lava Cap	Grass Valley-Nevada City.	Nevada	2	Lava Cap Gold Mining Corporation.	Gold ore.
3	Columbia No. 2	Resting Springs	Inyo	6	Shoshone Mines, Inc.	Lead ore.
4	Golden Queen	Mojave	Kern	3	Golden Queen Mining Co.	Gold ore.
5	Pine Creek	Bishop Creek	Inyo	19	United States Vanadium Corporation.	Tungsten-molybdenum-copper ore.
6	Essex-Columbia (Darwin Lead).	Coso	do	16	Imperial Metals, Inc.	Silver ore and lead ore.
7	Kelly	Randsburg	San Bernardino.	7	Frank W. Royer	Silver ore.
8	Empire Star mines	Grass Valley-Nevada City.	Nevada	8	Empire Star Mines Co., Ltd.	Gold ore.
9	Alabama	Ophir	Placer	9	Alabama California Gold Mines Co.	Do.
10	Idaho Maryland-Brunswick.	Grass Valley-Nevada City.	Nevada	17	Idaho Maryland Mines Corporation.	Do.

Copper.—Copper production in California was small in 1942 because the Walker mine in the Genesee district of Plumas County, which had contributed over 92 percent of the State copper in 1941, was inactive. The leading copper producer for 1942 was the Pine

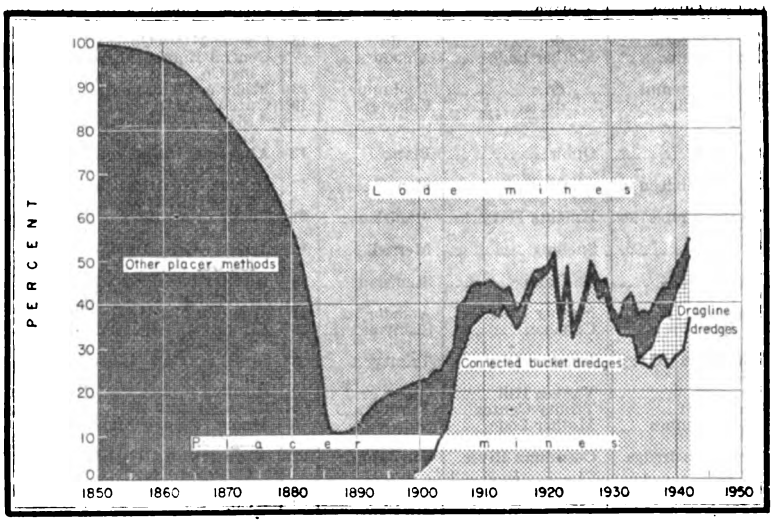

FIGURE 2.—Percentage of total California gold produced at lode and placer mines and by various methods of placer mining, 1850–1942.

Creek mine of the United States Vanadium Corporation, in the Bishop Creek district of Inyo County, where copper concentrate was recovered as a byproduct from ore worked principally for tungsten. In October, however, the Keystone Copper Co. made an initial shipment of copper concentrate from Copperopolis in Calaveras County; by the end of the year, the company attained the highest production rate of any mine in the State. Development work at copper proper-

Digitized by Google

ties was carried on by the Gray Eagle Copper Co. near Happy Camp in Siskiyou County, where a 550-ton plant was under construction, and by the Mountain Copper Co., Ltd., near Kennett in Shasta County, with a 350-ton plant under construction.

Lead.—The expansion in California's lead production from 990,000 pounds in 1938 to 10,302,000 pounds in 1942 resulted in lead displacing copper as the third most valuable of the five metals produced in the State. The Shoshone Mines, Inc., operator of the Columbia No. 2 mine, was the leading producer, and the Imperial Metals, Inc., operator of a group of mines at Darwin, was the second-largest lead producer; both operations are in Inyo County.

Zinc.—Zinc production in California, although still very small, continued to expand for the fourth successive year. The Combined Metals Reduction Co., operator of the Colorado group in the Modoc district of Inyo County, and W. F. Huston, operator of the Carbonate King mine in the Ivanpah district of San Bernardino County, contributed 77 percent of the State total.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in California in 1942, by counties, in terms of recovered metals

[1] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.
[2] Output from property not classed as a "mine."
[3] Combined to avoid disclosure of individual output.

MINING INDUSTRY

The tonnage of material from lode mines in California treated in 1942 decreased 42 percent compared with 1941, and the yardage at placer mines decreased 29 percent; the output of lode gold declined 45 percent and that of placer gold 35 percent. The average recoverable gold content of gravels declined 8 percent. Of the State total gold output in 1942, 45 percent was from lode mines and 55 percent from placers; this represented the highest placer : lode ratio since 1900, when separate annual data were first compiled, and almost certainly the highest since large-scale hydraulicking was terminated by the Sawyer Decision of 1884.

Dredges of the connected-bucket type washed 78 percent of the gravel mined and recovered 67 percent of the State total placer gold in 1942.

Dragline dredging, which had had such a spectacular rise during the years following its inception in California in 1933, reacted most unfavorably to war conditions; gold production by this method decreased 48 percent. The great demand for dragline excavators and for labor skilled in earth-moving caused rapid abandonment of dragline-dredge operations. The following table gives partial data on equipment in the dragline industry over a 4-year period; information on bucket size was supplied for 52 dredges in 1939, 89 in 1940, 94 in 1941, and 72 in 1942.

Size of buckets (cubic yards)	Number of boats				Size of buckets (cubic yards)	Number of boats			
	1939	1940	1941	1942		1939	1940	1941	1942
7½		1			1¾	2	3	8	5
6	1		2	1	1½	17	25	19	17
5		2	6	7	1¼	5	9	6	4
4		1			1	4	9	6	3
3½	1				⅞			1	
3	3	4	5	7	¾	1	7	8	6
2½	4	8	19	12	⅝	2	3		
2¼	2	1	1	1	⅜		1		
2	10	15	13	9					

Digitized by Google

Other placer-mining methods all showed decreases in quantity of gravel washed and gold recovered. The only gold credited to the Becker-Hopkins type of dredging resulted from the clean-up of a dredge, which suspended operations in 1941. Nonfloating washing plants to which gravel was delivered by mechanical means (dragline excavators, power shovels, slackline excavators, trucks, bulldozers) treated much less gravel in 1942 than in 1941. Many of these operators found that their equipment could be employed more profitably on war contracts; competition for labor skilled in operating earth-moving machines was very keen.

Suction dredging, which to date in California has been confined almost entirely to Fresno and Madera Counties, seemed to be expanding early in 1942, but by the end of the year these operations were largely suspended. The prospect that new techniques developed in relatively small scale suction dredging would be applied more widely in California after the war seemed favorable.

Hydraulic mining at established mines found itself singularly free from shortages of materials and power, but labor conditions caused marked reductions in operations. Very few hydraulic mines reopened for the 1942–43 season. Gold production from small-scale hand methods was sharply curtailed. In normal times, a large number of such operations are carried on independently by marginal workers, but the increasing labor shortage in California in 1942 caused many small-scale hand miners to abandon the streams and dry diggings for employment at wages. Drift mining, once very productive in California, also declined owing to war conditions.

Consumption of quicksilver at California placer mines totaled 13,944 pounds in 1942 compared with 19,949 pounds in 1941. The following quantities of gold were recovered to the pound of quicksilver used in 1942 (1941 figures in parentheses): Connected-bucket dredging, 34 ounces (40); dragline dredging, 40 ounces (37); suction dredging, 15 ounces (13); nonfloating washing plants with mechanical gravel handling, 17 ounces (42); hydraulicking, 16 ounces (22); small-scale hand operation, 18 ounces (15); and drift mining, 146 ounces (72).

ORE CLASSIFICATION

Of the 2,503,198 tons of ore (including 625,564 tons of old tailings) sold or treated in 1942, 82 percent was dry gold ore and old tailings, 16 percent copper ore (including a large quantity of ore valued more for its tungsten and molybdenum than copper), 1 percent lead ore, and most of the remainder dry silver ore.

Details of ore classification are given in the chapter of this volume on Gold and Silver.

[1] Includes ore valued principally for tungsten and molybdenum.
[2] Includes 71,100 pounds from precipitates.
[3] Includes metals recovered from tungsten ore.

METALLURGIC INDUSTRY

During 1942, as in former years, most of the ore and virtually all the old tailings were treated at amalgamation and cyanidation mills (with or without concentrating equipment); 80 percent of the total ore and old tailings was treated at such mills in 1942. Almost all the remaining ore was treated at concentrating mills; only 60,395 tons of crude ore were shipped for direct smelting. Smelters also received 21,314 tons of flotation concentrates and 288 tons of gravity concentrates from California mine operators. Comparing 1942 with 1941, material treated at amalgamation mills decreased 63 percent, material treated at cyanidation mills decreased 55 percent, and quantity of crude ore and old tailings smelted increased 35 percent; the quantities of ore concentrated in 1941 and 1942 are not comparable because a substantial quantity of tungsten ore was included in the latter year and excluded in the former.

Quicksilver consumption at California amalgamation mills totaled 3,040 pounds, used in the treatment of 785,945 tons of material to recover 144,004 ounces of gold and 29,010 ounces of silver in 1942. In the treatment of 503,551 tons of ore, 135,896 tons of old tailings, and 5,918 tons of concentrates to recover 106,092 ounces of gold and 344,476 ounces of silver, cyanide consumption was 110,701 pounds of 91-percent sodium cyanide and 744,246 pounds of commercial calcium cyanide (50-percent NaCN equivalent); in terms of 98-percent NaCN, the consumption was 467,475 pounds or 0.72 pound to the ton. A substantial part of the cyanide was consumed at custom mills in California.

Companies producing most of California's lode gold in 1942 owned and operated their own metallurgical plants, but a number of custom mills were active. The leading operators of metallurgical plants receiving custom material were: Burton Bros., Inc., Rosamond, Kern County; Golden Queen Mining Co., Mojave, Kern County; Mineral Reduction Co., Benton, Mono County; and F. W. Royer, Red Mountain, San Bernardino County. All these mills were cyanidation plants

Digitized by Google

and accepted ore and old tailings for treatment. The Idaho Maryland Mines Corporation and Empire Star Mines Co., Ltd., Grass Valley, Nevada County, cyanided some lots of concentrates. The zinc oxide plant of the Pacific Zinc Oxide Co. (formerly Western Zinc Oxide Co.), Richmond, Contra Costa County, which had treated oxidized zinc ores in 1941, suspended operations early in 1942. The largest metallurgical custom plant in California—the Selby lead plant of the American Smelting & Refining Co. at Selby, Contra Costa County—continued to be the State's only smelter. By the end of the year, all these custom plants except the Selby smelter had suspended operations.

Mine production of metals in California in 1942, by methods of recovery, in terms of recovered metals

[1] Only those districts shown separately for which Bureau of Mines is at liberty to publish figures; others producing listed in footnote 18 and their output included under "Other districts."
[2] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.
[3] Source of total silver as follows: 1,409,805 ounces from lode mines and 40,635 ounces from placers.
[4] Camanche district lies in Amador, Calaveras, and San Joaquin Counties.
[5] East Belt district lies in Amador, Calaveras, Eldorado, Mariposa, and Tuolumne Counties.
[6] Mother Lode district lies in Amador, Calaveras, Eldorado, Mariposa, and Tuolumne Counties.
[7] Output of property not classed as a "mine."
[8] Jenny Lind district lies in Calaveras and San Joaquin Counties.
[9] West Belt district lies in Calaveras, Eldorado, and Tuolumne Counties.
[10] Randsburg district lies in Kern and San Bernardino Counties.
[11] White River district lies in Kern and Tulare Counties.
[12] Chowchilla River district lies in Madera and Merced Counties.
[13] Hunter Valley district lies in Mariposa and Merced Counties.
[14] Dale district lies in Riverside and San Bernardino Counties.
[15] Included under "Other districts."
[16] Exclusive of placer output, which is included under "Other districts."
[17] Exclusive of lode output, which is included under "Other districts."
[18] Includes following: Bishop Creek district in Inyo County; Daulton in Madera County; Bodie in Mono County; Rich Bar in Plumas County; Ivanpah in San Bernardino County; Figueroa Mountain in Santa Barbara County; Flat Creek, French Gulch (placer), and Redding (placer) in Shasta County; Brandy City and Downieville (lode) in Sierra County; Humbug (placer) in Siskiyou County; Knights Ferry in Stanislaus County; Coffee Creek (lode) and Trinity Center (placer) in Trinity County; and Yuba River in Yuba County.
[19] Includes 71,000 pounds from precipitates.

AMADOR COUNTY

East Belt district.—The Belama Corporation worked the Belden mine in the Volcano section of the East Belt from January 1 until November 23, 1942. A lessee operated the Elk Horn mine from January 1 to May 1; 166 tons of gold ore containing 407 ounces of gold, 189 ounces of silver, and 2,621 pounds of copper were shipped to a smelter. Gold ore from the Fort Ann mine was amalgamated. The Garibaldi or Boardman property was operated by dragline and dry-land dredging; the dragline dredge recovered 775 ounces of gold and 102 ounces of silver from 172,200 cubic yards of gravel; and the dry-land dredge recovered 157 ounces of gold and 23 ounces of silver from 35,500 cubic yards of gravel.

Mother Lode district.—The Argonaut Mining Co., Ltd., suspended operations at the Argonaut mine March 31, 1942; gold ore was treated by amalgamation and flotation, and the concentrates were cyanided. The company also operated a 500-ton flotation plant at the Plymouth old tailings dump. While the Argonaut cyanide plant was in operation, the concentrates from the Plymouth old-tailings operation were cyanided but were shipped to a smelter later in the year. The Central Eureka Mining Co. operated the Old Eureka and Central Eureka mines from January 1 to October 1; ore was treated by amalgamation and flotation, and the sands and concentrates were cyanided. The Kennedy Mining & Milling Co. operated the Kennedy mine until War Production Board Order L–208 ended operations which had been continuous since 1886. Lorentz & Swingle and the Long Bar Gold Dredging Co. operated dragline dredges on the Lorentz property on Cosumnes River; the company recovered 1,140 ounces of gold and 138 ounces of silver from 200,000 cubic yards of gravel. The Long Bar company also operated a dragline dredge on the Pension mine from September 13 to 28; 14,000 cubic yards of gravel yielded 87 ounces of gold and 12 ounces of silver. J. C. Pantle operated a dry-land dredge on the Rupley ranch on Willow Creek 5 miles west of Drytown from January 1 until October 15; 230,000 cubic yards of gravel yielded 1,290 ounces of gold and 183 ounces of silver; gravel was delivered to the dry-land dredge by a dragline excavator equipped with a 1½-cubic yard bucket.

BUTTE COUNTY

Butte Creek district.—The Lancha Plana Gold Dredging Co. operated a connected-bucket dredge on Butte Creek from January 1 to October 12, 1942; the dredge was of the Yuba type and had 65 4½-cubic foot buckets.

Oroville district.—F. C. Peterson operated a nonfloating washing plant on the Amo mine during 1942; 60,000 cubic yards of gravel yielded 379 ounces of gold and 12 ounces of silver. Yuba Consolidated Gold Fields, Butte Unit, operated four connected-bucket dredges on land adjoining Feather River from January 1 to October 15; all dredges were of the Yuba type and used electric power. The dredge-bucket equipment per boat was: 84 9-cubic foot, 89 9-cubic foot, 87 9-cubic foot, and 71 6-cubic foot buckets. The Golden Feather Dredging Co. operated a dragline dredge on the Feather River channel at Oroville throughout 1942. Because this operation cleared the channel of the river and stacked tailings along the levees, the company was permitted to continue operations after War Production Board

Digitized by Google

Order L–208 became effective. The Placer Exploration Co. and Sunmar Dredging Co. operated dragline dredges on the Gianella property for short periods. The Placer Exploration Co. also carried on dragline dredging on the Innis property. In addition to the Gianella operation, the Sunmar Dredging Co. worked the Peter property. The Morris Ravine Mining Co. washed 850 cubic yards of gravel from which 658 ounces of gold and 65 ounces of silver were recovered; the gravel was recovered by drift mining.

Yankee Hill district.—Hoefling Bros. operated the Surcease mine from January 1 to November 15, 1942; 27,480 tons of gold ore were treated in a 125-ton flotation-cyanidation mill; 713 ounces of gold and 89 ounces of silver were recovered by amalgamation of high-grade jig concentrates, and 6,630 ounces of gold and 15,907 ounces of silver were recovered by cyanidation of sands, slimes, and reground concentrates. Hoefling Bros. explored the nearby Big Bend prospect and, when War Production Board Order L–208 went into effect, intended to utilize the company organization and mill to develop the Big Bend zinc-copper ores.

CALAVERAS COUNTY

Camanche district.—The Cat Camp Placers and Burson Mining Co. operated the Cat Camp mine during 1942; 71,818 cubic yards of gravel treated in nonfloating washing plants yielded 483 ounces of gold and 32 ounces of silver. E. A. Bacon recovered 286 ounces of gold and 14 ounces of silver from 10,000 cubic yards of gravel near Wallace; hydraulicking and a mechanical excavator were used.

Copperopolis district.—The Keystone Copper Co. unwatered and reopened the north shaft of the Keystone mine and started production in October 1942; 12,208 tons of copper ore were treated by flotation in the redesigned gold mill at the nearby Mountain King mine, and 1,619 tons of copper concentrates were shipped; the concentrates contained 15 ounces of gold, 602 ounces of silver, and 542,380 pounds of copper.

Mother Lode district.—The Carson Hill Gold Mining Corporation treated 144,954 tons of gold ore at the Carson Hill mine between January 1 and May 31, 1942, and produced amalgamated bullion containing 4,173 ounces of gold and 404 ounces of silver; cyanidation bullion containing 5,242 ounces of gold and 2,400 ounces of silver; and 122 tons of gravity concentrates which, after partial extraction by amalgamation, contained 1,188 ounces of gold and 1,596 ounces of silver, when delivered to a smelter. On May 31 a fire destroyed the crushing, grinding, and flotation parts of the mill, and production was not resumed thereafter. According to the company printed annual report for the year ended September 30, 1942, the average recovery was $2.18 per ton as compared with $2.15 and $2.19 for the years ended September 30, 1941 and 1940, respectively. According to the company engineer's report as of June 1, 1942, ore reserves in the Morgan Melones mine are estimated at 940,500 tons of a grade equal to that milled during the last 6 months of operation and 1,984,000 tons in the Calaveras mine of a grade estimated at $5.76 per ton. W. Clark subleased the Val ranch and operated a stationary washing plant, to which gravel was delivered by power shovel and trucks, from May 7 to October 19; 6,245 cubic yards of gravel yielded 69 ounces of gold and 7 ounces of silver.

Digitized by Google

West Belt district.—E. A. Vogt carried on development work at the Collier mine during 1942 and shipped small lots of zinc and gold-silver ores. The property received a Reconstruction Finance Corporation Class B development loan October 12. In the same district the Mountain Copper Co., Ltd., and the Quail Hill Mining Co. conducted exploration campaigns at the Napoleon and Quail Hill mines, respectively. The ore bodies under development in the district contained zinc, copper, gold, and silver.

ELDORADO COUNTY

Mother Lode district.—Alhambra-Shumway Mines, Inc., worked the Alhambra mine from March 1 to November 1, 1942; 2,305 tons of ore treated in the company 25-ton amalgamation mill yielded bullion containing 505 ounces of gold and 74 ounces of silver and 6 tons of flotation concentrates containing 34 ounces of gold and 3 ounces of silver. G. W. Gray recovered 80 ounces of gold and 5 ounces of silver from 1,000 pounds of quartz removed from a pocket at the Guttenberger property near Diamond Springs. The Barker Corporation operated a dragline dredge on the Explorers property from January 1 to August 29; 95,000 cubic yards of gravel yielded 754 ounces of gold and 94 ounces of silver. At the Good Luck mine 23,000 cubic yards of gravel yielded 164 ounces of gold and 22 ounces of silver; 14,000 cubic yards of gravel washed at the Max & Junction mine yielded 110 ounces of gold and 15 ounces of silver; 77,500 cubic yards of gravel washed at the Setter property yielded 548 ounces of gold and 70 ounces of silver.

West Belt district.—C. D. Jones operated the Boulder mine in the Rescue section of the West Belt from March to October 15, 1942; 280 tons of gold ore treated by amalgamation yielded 122 ounces of gold and 13 ounces of silver. The Big Canyon Dredge operated a dragline dredge from January 1 to July 31; 1,269 ounces of gold and 137 ounces of silver were recovered from 250,000 cubic yards of gravel; the dragline excavator was equipped with a 3-cubic yard bucket.

FRESNO COUNTY

Friant district.—Griffith Co. and Bent Co., which supplied gravel for the Friant Dam in 1942, recovered 205 ounces of gold and 29 ounces of silver in preparing 121,700 cubic yards of sand and gravel. The Twin Bar Mining Corporation operated a dredge on the Grant Pacific Rock and V. Roulard properties from March to October 23. Hopkins & Becker operated a suction dredge on San Joaquin River near Friant. The Grant-Service Rock Co. recovered 114 ounces of gold and 16 ounces of silver in preparing 339,955 tons of sand and gravel for concrete aggregate.

IMPERIAL COUNTY

Mesquite Diggings (Glamis) district.—Van Derpoel & Murphy operated the Mary Lode mine from January 1 to July 15, 1942, when operations were suspended because of war conditions; 186 tons of ore treated in the company 25-ton amalgamation-cyanidation mill yielded 109 ounces of gold and 136 ounces of silver.

Digitized by Google

INYO COUNTY

Bishop Creek district.—The United States Vanadium Corporation produced by flotation a copper concentrate containing a substantial quantity of silver per ton as a byproduct of ore treated primarily for tungsten. This company was the leading copper producer in the State in 1942.

Cerro Gordo district.—Desert Miners shipped zinc-lead ore from the Leary mine in the Swansea section of the Cerro Gordo district during 1942.

Coso (Darwin) district.—The Imperial Metals, Inc., operated the Defiance, Independence, Essex, Thompson, Lucky Jim, Lane, Promontory, and Columbia mines as a unit during 1942; a newly constructed 150-ton gravity-concentration and flotation mill began operations June 20 and continued until November 23, when unsatisfactory metallurgical results and inability to hire experienced workmen forced suspension of milling. In addition, the company made shipments of crude ore, which were continued after mill operations were suspended. The milling of 11,415 tons of silver ore produced 790 tons of lead concentrates, containing 57 ounces of gold, 22,989 ounces of silver, and 612,000 pounds of lead; shipments of 2,823 tons of lead ore contained 117 ounces of gold, 26,887 ounces of silver, and 850,000 pounds of lead.

Modoc district.—The Combined Metals Reduction Co. operated the Colorado group throughout 1942; zinc sulfide ore was shipped to the company concentrating mill at Bauer, Utah.

Resting Springs district.—Shoshone Mines, Inc., shipped ore from the Columbia No. 2 mine throughout 1942 and was by far the largest producer of lead and third-largest producer of silver in the State; 24,999 tons of ore contained 4,770 ounces of gold, 210,503 ounces of silver, 14,710 pounds of copper, 8,425,760 pounds of lead, and 2,789,540 pounds of zinc.

Sherman district.—Burton Bros. (partnership) operated the Ruth mine and treated 19,961 tons of ore by crushing and cyanide leaching in 1942; 3,674 ounces of gold and 102 ounces of silver were recovered before operations were suspended November 1 because of War Production Board Order L–208.

Slate Range district.—L. E. Damon shipped lead ore from the Gold Bottom mine during 1942. C. O. Mittendorf, lessee, operated the Ophir mine through sublessees from January to September and shipped to a smelter 501 tons of lead ore containing 4 ounces of gold, 2,215 ounces of silver, and 246,440 pounds of lead.

South Park district.—The Southwest Lead & Zinc Co. operated the Honolulu mine from April 1 to December 31, 1942, and shipped zinc-lead and lead ores to a smelter.

KERN COUNTY

Cove district.—Kern Mines, Inc., operated the Big Blue mine from January 1 to July 1, 1942; 16,467 tons of ore yielded amalgamation bullion, containing 1,054 ounces of gold and 460 ounces of silver, and 346 tons of flotation concentrates, containing 1,271 ounces of gold, 4,180 ounces of silver, and 11,216 pounds of lead.

Mojave district.—The Cactus Mines Co. operated the Cactus Queen mine in the Middle Buttes section of the Mojave district from January

Digitized by Google

1 to November 20, 1942, and treated gold-silver ore in the company 125-ton cyanidation-flotation mill; the resulting concentrates were shipped to a smelter. This property was California's leading silver producer for the fifth successive year. Lessees shipped 950 tons of gold ore from the Elephant-Eagle mine to nearby custom cyanide mills; 612 ounces of gold and 71 ounces of silver were recovered. Lessees worked the Middle Butte mine; 125 tons of ore treated by amalgamation, 165 tons of ore shipped to a custom cyanide mill, and 175 tons of old tailings cyanided yielded amalgamation bullion containing 15 ounces of gold and 4 ounces of silver and cyanide bullion containing 68 ounces of gold. Burton Bros., Inc., operated the Tropico mine from January 1 to November 1; 18,044 tons of gold ore treated in the company 100-ton cyanide mill yielded 5,353 ounces of gold and 11,850 ounces of silver. In addition, the company treated over 4,783 tons of custom material from 65 shippers during 1942 compared with over 8,800 tons of custom material from 215 shippers in 1941. When the Burton Bros., Inc., mill ceased to accept custom ores, a number of mines within a radius of 100 or more miles of Rosamond were left without an economic market for their ores, as all other custom mills in the region had alread discontinued milling.

Randsburg district.—E. B. Atkinson shipped 357 tons of ore from the Earl & Matilda mine to a custom cyanide mill in 1942; 68 ounces of gold and 11 ounces of silver were recovered. S. D. Fraser and lessees operated the K. C. N. mine from January 1 to August 15; 234 tons of ore shipped to custom cyanide mills yielded 175 ounces of gold and 8 ounces of silver. King Solomon Mines Lease worked the King Solomon mine from January 1 to April 30; 285 tons of ore treated by amalgamation yielded 76 ounces of gold and 21 ounces of silver, and 150 tons of old tailings treated by cyanidation yielded 7 ounces of gold and 3 ounces of silver. The Anglo American Mining Corporation, Ltd.—largest operator in the Randsburg district—treated 300,755 tons of old tailings and recovered 6,075 ounces of gold and 2,691 ounces of silver from January 1 to October 23, when operation was suspended by War Production Board Order L–208. The Rand Gold Dredging Associates installed a connected-bucket-type dredge with 82 3-cubic foot buckets to work gravels at a property 1¼ miles northwest of Randsburg; the dredge was moved from Shasta County, where it had formerly been operated by the Roaring River Dredging Co. The dredge was reconstructed and jigs were added in order to recover scheelite as well as gold; operations started November 1. The Monarch Rand Mining Co. operated a dry-land dredge for the recovery of scheelite and gold intermittently over a 6-month period.

LOS ANGELES COUNTY

Cedar district.—The Governor Mine Co. turned over operation of the Governor and Red Rover mines to G. Moore February 16, 1942, and all work was suspended October 15; during the year 870 tons of ore were treated by amalgamation and flotation in the company 135-ton mill; 78 ounces of gold and 15 ounces of silver were recovered in bullion, and 14 tons of concentrates shipped to a smelter contained 39 ounces of gold and 24 ounces of silver.

Digitized by Google

MADERA COUNTY

Daulton district.—The West Lode Reduction Co. pumped copper-bearing water from the Daulton mine, which was percolated through old dumps at the property and the copper precipitated on scrap iron during 1942; the cement copper was shipped to a manufacturer of copper sulfate. Copper ore from the Jessie Bell mine was shipped to a copper smelter.

Potter Ridge district.—G. E. Noble & Sons operated a suction dredge on the J. T. Pierce ranch from January 1 to December 12, 1942; 7,790 cubic yards of gravel yielded 118 ounces of gold and 35 ounces of silver. Suction-dredge operations on the Polk ranch recovered 148 ounces of gold and 32 ounces of silver from 9,000 cubic yards of gravel.

MARIPOSA COUNTY

East Belt district.—R. J. Wilson operated the Feliciana mine throughout 1942; 3,211 tons of gold ore treated by amalgamation and concentration in a 25-ton mill yielded amalgamation bullion containing 1,535 ounces of gold and 236 ounces of silver and 49 tons of flotation concentrates containing 403 ounces of gold and 78 ounces of silver; the concentrates were shipped to a smelter. Schroeder, Odgers & Schroeder worked the Schroeder mine in the Colorado section of the East Belt throughout the year; 39 tons of gold ore treated in a 20-ton Huntington mill yielded 716 ounces of gold and 88 ounces of silver. The Whitlock mine was active.

Hunter Valley district.—E. L. Buerki operated the Ruth Pierce mine throughout 1942 and treated 1,620 tons of old tailings, which yielded 94 ounces of gold and 59 ounces of silver; the old tailings were given a 96-hour leach in a 15-ton plant. Thurman & Wright operated a dragline dredge on Burns Creek from January 1 to August 20; the dragline-excavator equipment included 4½- and 6-cubic foot buckets. The Trebor Corporation, which suspended operations at the Gaskill property on Corbett Creek 8 miles west of Mariposa December 30, 1941, shipped 68 ounces of gold and 12 ounces of silver from the final clean-up of the operation; the dragline excavator was equipped with a 2-cubic yard bucket. The Barker Corporation operated a dragline dredge on the Kehoe, J. Lord, and Trabucco properties between January 1 and July 1, 1942; 22,000 cubic yards of gravel washed at the Kehoe property yielded 112 ounces of gold and 32 ounces of silver; 109,000 cubic yards of gravel at the J. Lord property yielded 833 ounces of gold and 229 ounces of silver; and 163,500 cubic yards of gravel at the Trabucco property yielded 1,016 ounces of gold and 280 ounces of silver.

Mother Lode district.—The Mount Gaines Mining Co. worked the Mount Gaines mine throughout 1942; 11,263 tons of gold ore yielded amalgamation bullion containing 3,664 ounces of gold and 1,134 ounces of silver and 337 tons of flotation concentrates containing 3,281 ounces of gold, 1,117 ounces of silver, 2,027 pounds of copper, and 583 pounds of lead; the concentrates were shipped to a smelter. The Pacific Mining Co. worked the Pine Tree and Josephine mines; 50,697 tons of ore yielded amalgamation bullion containing 233 ounces of gold and 52 ounces of silver and 959 tons of flotation concentrates containing 6,056 ounces of gold, 1,450 ounces

Digitized by Google

of silver, and 1,213 pounds of copper. The Trebor Corporation operated the C. C. Pierce property on Corbett Creek for 3½ months in 1942; 100,000 cubic yards of gravel yielded 289 ounces of gold and 57 ounces of silver; the equipment was the same as that used on another section of Corbett Creek in the Hunter Valley district.

MERCED COUNTY

Snelling district.—The Merced Dredging Co. operated a connected-bucket dredge with 60 9½-cubic foot buckets on Merced River ¾ of a mile southeast of Snelling from January 1 to October 13, 1942. The San Joaquin Mining Co. operated a connected-bucket dredge in the Merced River Valley 3 miles southwest of Snelling from January 1 to October 14; the dredge was equipped with 64 9½-cubic foot buckets. The Snelling Gold Dredging Co. began 1942 with two dredges operating on Merced River between Snelling and Merced Falls; dredge No. 1 with 66 7-cubic foot buckets was closed down March 31, and dredge No. 2 with 72 7-cubic foot buckets suspended operations October 15 because of War Production Board Order L–208.

MONO COUNTY

Blind Springs district.—Conversion of the Mineral Reduction Co. cyanide-flotation custom mill from the treatment of gold and silver ores to tungsten ores early in 1942 left many of the mines in the Blind Springs district and surrounding territory without a market for their ores.

NEVADA COUNTY

Grass Valley-Nevada City district.—The Empire Star Mines Co., Ltd., operated the Empire, North Star, and Pennsylvania mines at Grass Valley in Nevada County and the Pennsylvania and Dannebrog at Browns Valley in Yuba County during 1942; in addition, work on a tailings-disposal adit from the South Fork of Yuba River near Omega to the Zeibright mine was carried on during the early months of the year. Ore mined in the Empire-North Star-Pennsylvania group was treated in the company amalgamation-cyanidation-flotation mill; all productive operations were suspended by War Production Board Order L–208, but a crew of over 100 men was retained for maintenance purposes. The Idaho Maryland Mines Corporation operated the Idaho Maryland-Brunswick group from January 1 to October 15; according to the company printed annual report for the year ended December 31, 1942, 144,639 tons of ore yielded 53,342 ounces of gold and 14,700 ounces of silver. Of the year's total tonnage, 17.4 percent was derived from development or exploration and the remainder from stoping. The Brunswick mill was closed April 30, and one of the two units of the Idaho mill was operated part time. During the year the new Brunswick steel head frame, crusher plant, hoist, and compressor buildings were completed; this equipment was designed to handle 2,000 tons a day from depths of 5,000 feet. Increasing labor shortages curtailed production. When War Production Board Order L–208 went into effect, 245 men were employed compared with a daily average of 1,000 men in 1940; after the order the crew was reduced to 125 men for mine and plant maintenance. The Lava Cap Gold Mining Corporation operated the Lava Cap

Digitized by Google

mine throughout 1942; 137,194 tons of ore were treated by amalgamation, flotation, and cyanidation in the company 400-ton flotation plant, 25-ton concentrate- and middling-cyanide plant, and 350-ton tailings-cyanide plant. Cyanidation of sands, slimes, and middlings yielded 2,245 ounces of gold and 15,558 ounces of silver; amalgamation of high-grade ore yielded 113 ounces of gold and 29 ounces of silver; 4,912 tons of flotation concentrates shipped to a smelter contained 30,804 ounces of gold, 233,130 ounces of silver, 21,048 pounds of copper, and 13,600 pounds of lead.

North Bloomfield district.—A. B. Innis operated a dragline dredge at the Malakoff mine during 1942; 146,000 cubic yards of gravel yielded 694 ounces of gold and 64 ounces of silver.

Washington district.—The Omega Co. and lessees operated the Omega mine from January 17 to July 7, 1942; 818,175 cubic yards of gravel yielded 1,749 ounces of gold and 54 ounces of silver.

ORANGE COUNTY

Santa Rosa district.—The Blue Light Silver Mines Co. worked the Silverado or Blue Light mine in Silverado Canyon from January to June 1942; 100 tons of silver ore treated by flotation yielded 5 tons of lead concentrates containing 2 ounces of gold, 470 ounces of silver, 2,538 pounds of lead, and 1,517 pounds of zinc, and 7 tons of zinc concentrates containing 80 ounces of silver and 7,596 pounds of zinc; the concentrates were shipped to smelters. In addition, 18 tons of silver ore, containing 3 ounces of gold and 2,195 ounces of silver, were shipped to a smelter. The Ortega Mining Co. shipped argentiferous lead ore from the district.

PLACER COUNTY

Auburn district.—G. M. Trent shipped to a smelter 43 tons of gold-silver ore containing 9 ounces of gold, 150 ounces of silver, 776 pounds of copper, and 670 pounds of lead while developing the Valley View mine during 1942.

Ophir district.—The Alabama California Gold Mines Co. operated the Alabama mine from January to August 1942; ore was treated by amalgamation and flotation, and the resulting concentrates were shipped to a smelter; amalgamation bullion contained 8,391 ounces of gold and 2,575 ounces of silver, and 496 tons of flotation concentrates contained 2,149 ounces of gold, 25,919 ounces of silver, 5,442 pounds of copper, and 25,927 pounds of lead. Exploration and development continued at the Ophir mine from January 1 until September 1; test runs were made by amalgamation, cyanidation, concentration, and direct smelting on small tonnages of ore; in all, 184 tons of ore yielded 86 ounces of gold, 196 ounces of silver, and 3,288 pounds of copper. The Oro Fino Consolidated Mines operated the Oro Fino mine from January 1 to October 8; 9,058 tons of ore treated in the company 200-ton amalgamation-flotation mill yielded amalgamation bullion containing 3,535 ounces of gold and 1,423 ounces of silver; and 125 tons of concentrates, which were cyanided in the custom cyanide plant, yielded 522 ounces of gold and 224 ounces of silver.

Digitized by Google

PLUMAS COUNTY

Greenville (Crescent Mills) district.—Cherokee Mine operated the Cherokee property from January 1 to July 15, 1942, when the property was abandoned; 13,392 tons of ore treated by cyanidation yielded 2,331 ounces of gold and 59 ounces of silver.

SACRAMENTO COUNTY

Cosumnes River district.—The Cosumnes Gold Dredging Co. operated a connected-bucket dredge 7 miles southwest of Sloughhouse from January 1 to October 20, 1942; the dredge used electric power and was equipped with 63 12-cubic foot buckets. Hoosier Gulch Placers operated two dragline dredges in the Cosumnes River district during 1942. The Humphreys Gold Corporation operated a dragline dredge on Cosumnes River from January 1 to April 6; the floating washing plant was served by four dragline excavators, each equipped with a 2½-cubic yard bucket, which stripped overburden as well as delivered auriferous gravel to the plant.

Folsom district.—The Capital Dredging Co. operated two electric connected-bucket dredges on its property 5 miles south of Folsom from January 1 to October 15, 1942; one dredge had 88 and the other 100 18-cubic foot buckets. The General Dredging Co. operated three dragline dredges, one near Folsom, the second near Natoma, and the third near Fair Oaks. Cutter & Mueller and the Pacific Coast Aggregates, Inc., recovered gold as a byproduct in the operation of a commercial sand and gravel plant at Fair Oaks; Cutter & Mueller recovered 183 ounces of gold and 15 ounces of silver from 40,320 cubic yards of gravel, and Pacific Coast Aggregates, Inc., recovered 111 ounces of gold and 11 ounces of silver. The Lancha Plana Gold Dredging Co. operated a dragline dredge at Sailor's Bar on American River from January 1 to November 11, 1942. The Natomas Co. operated a fleet of seven electric connected-bucket dredges at and near Natoma from January 1 to October 15. The number and size of buckets per dredge were: No. 1, 62 16-cubic foot; No. 4, 67 15-cubic foot; No. 5, 105 12-cubic foot; No. 6, 106 11-cubic foot; No. 7, 98 9-cubic foot; No. 8, 105 12-cubic foot; and No. 10, 83 15-cubic foot.

SAN BERNARDINO COUNTY

Buckeye district.—The Bagdad-Chase, Ltd., operated the Bagdad-Chase mine from January 1 to December 31, 1942; gold ore, containing a substantial quantity of silver and copper, was shipped to a smelter.

Calico district.—M. La Jeunesse operated a cyanide-leaching plant on wind-blown tailings from the Calico tailings dump from January 1 to May 15, 1942; 370 tons of old tailings yielded 1,084 ounces of silver. L. Coke shipped silver ore from the Zenda mine.

Dale district.—L. A. Wilson operated the Glad-Stone, Gold-Stone, and Desert-Gold mining claims from January 1 to June 2, 1942; 243 tons of ore, shipped to custom cyanide mills, yielded 371 ounces of gold and 125 ounces of silver.

Ivanpah district.—W. F. Huston operated the Carbonate King mine from January 1 to December 31, 1942; 749 tons of oxidized zinc

Digitized by Google

ore, containing 1 ounce of gold, 543 ounces of silver, 16,745 pounds of lead, and 567,163 pounds of zinc, were shipped to smelters.

New York Mountains district.—The California Sulphur Co. carried on development work at the Sagamore mine (Alpha claims) from June until December 31, 1942; 114 tons of lead ore, containing 1 ounce of gold, 682 ounces of silver, 3,481 pounds of copper, and 14,597 pounds of lead, were shipped to smelters.

SAN JOAQUIN COUNTY

Camanche district.—The Gold Hill Dredging Co. operated two electric connected-bucket dredges on the California Lands, Inc., Central Bank of Calaveras, Thorne, and Putnam properties during 1942; one dredge had 66 7¾-cubic foot buckets and the other 87 8½-cubic foot buckets. Both dredges ceased operations October 14, but one resumed work December 20 and continued until December 31. The Lobicasa Co. operated a dragline dredge, using a dragline excavator with a 1½-cubic yard bucket, on the Foster ranch from January 1 to May 14, when the property was worked out and abandoned. The Gold Valley Dredging Co. operated a dry-land washing plant, to which gravel was delivered by a gasoline dragline excavator with a ¾-cubic yard bucket, at the Murdoch ranch from February 25 to May 24; 9,316 cubic yards of gravel yielded 83 ounces of gold and 6 ounces of silver.

Jenny Lind (Bellota, Linden) district.—Smith-Notterman Co. operated a dragline dredge with a dragline excavator having a 1¾-cubic yard bucket on the Elmer Cady ranch from January to March 26, 1942; 93,105 cubic yards of gravel yielded 344 ounces of gold and 14 ounces of silver.

SHASTA COUNTY

Flat Creek district.—The Mountain Copper Co., Ltd., largest mineral producer in Shasta County, worked the Iron Mountain mine throughout 1942; oxidized ore was treated in the company 700-ton cyanide plant until plant operation was suspended in February. Mining of copper-bearing sulfide ores was begun in May, and shipments to a smelter continued during the rest of the year; in addition, the company was engaged in opening a large zinc-copper ore body and constructing a flotation mill for its treatment. A small quantity of gold, silver, and copper was recovered from smelting cinder derived from burning pyrites in a sulfuric acid plant; the pyrites was produced by the Mountain Copper Co., Ltd., at the Hornet mine.

Igo district.—B. H. K. Mines operated a dragline dredge, using a dragline excavator with a 1½-cubic yard bucket, on the R. C. Connely and R. Litsch properties on Clear Creek from January 1 to May 15, 1942; 120,000 cubic yards of gravel yielded 760 ounces of gold and 104 ounces of silver. The Lincoln Gold Dredging Co. operated a dragline dredge with a dragline excavator having a 2½-cubic yard bucket on the Brady property; 37,234 cubic yards of gravel yielded 162 ounces of gold and 26 ounces of silver. The Clear Creek Dredging Co. operated a dragline dredge on Clear Creek. The Crow Creek Dredging Co. operated a dragline dredge, using a dragline excavator with a 1½-cubic yard bucket, on Cottonwood Creek from January 1 to April 13, 1942; 100,000 cubic yards of gravel

Digitized by Google

yielded 580 ounces of gold and 20 ounces of silver. The Dobbin Gulch Dredging Co. operated a dragline dredge with a dragline excavator having a 1¼-cubic yard bucket on Roaring River from March 3 to June 2; 70,500 cubic yards of gravel yielded 169 ounces of gold and 11 ounces of silver. The Thurman Gold Dredging Co. operated a Yuba electric connected-bucket dredge, equipped with 72 9-cubic foot buckets, on Clear Creek from January 1 to October 14, 1942.

SIERRA COUNTY

Alleghany district.—The Original Sixteen to One Mine, Inc., operated its Original Sixteen to One mine throughout 1942; in addition to underground work, a lessee treated old tailings at the property. J. Sweeney operated the Snow Drift mine from March to September; 111 tons of ore yielded 145 ounces of gold and 23 ounces of silver.

Downieville district.—Wm. Richter & Sons operated a dragline dredge on Pacific Gas & Electric Co. property from January 1 to April 30; 58,000 cubic yards of gravel yielded 243 ounces of gold and 29 ounces of silver.

Pike (Slate Range) district.—H. L. Sorensen operated the Alaska mine from January 1 to October 10 and treated 388 tons of ore by amalgamation, which yielded 547 ounces of gold and 185 ounces of silver; during the year development was shifted from the Alaska to the Grizzly vein. W. C. Ennis operated the Bowman mine from January 1 to December 31; 3,140 tons of ore yielded 480 ounces of gold and 85 ounces of silver.

Poker Flat (Port Wine, Table Rock) district.—A. J. Just carried on hydraulicking at the Pioneer Project mine at Grass Flat for 10 days during 1942; 17,000 cubic yards of gravel yielded 71 ounces of gold and 4 ounces of silver. C. S. Poor worked the Tennessee Manxman drift mine throughout the year; 1,200 cubic yards of gravel yielded 142 ounces of gold and 16 ounces of silver.

SISKIYOU COUNTY

Callahan district.—The Okoro Mines, Inc., operated a dragline dredge on the Hayden property from January 1 to 31, 1942; 60,000 cubic yards of gravel yielded 103 ounces of gold and 10 ounces of silver.

Greenhorn district.—The Lincoln Gold Dredging Co. operated a dragline dredge on the City of Yreka, General Dredge, Marlow, Nunes, and Rose properties from January 1 to July 21, 1942; the dragline excavator was equipped with a 2½-cubic yard bucket. The following data on yardages washed and precious metal recovered were reported: City of Yreka property, 43,029 cubic yards of gravel yielded 304 ounces of gold and 44 ounces of silver; General Dredge property, 272,423 cubic yards of gravel, 1,844 ounces of gold and 263 ounces of silver; and Nunes property, 31,128 cubic yards of gravel, 259 ounces of gold and 37 ounces of silver.

Klamath River district.—The Gray Eagle Copper Co. reopened the Dakin copper mine near Happy Camp and constructed a 550-ton flotation mill during 1942; no shipments of ore or concentrates were made. The William von der Hellen Mining Co. operated a dragline dredge, using a dragline excavator with a 3-cubic yard bucket, on

Digitized by Google

McConnell Bar from January 1 to September 27; 596,800 cubic yards of gravel yielded 3,594 ounces of gold and 554 ounces of silver.

Liberty district.—N. Marvin worked the Hansen mine during 1942. A. Markon operated the Surprise mine on Eddys Gulch from March 2 to November 28, 1942; 148 tons of ore treated by amalgamation yielded 78 ounces of gold and 15 ounces of silver. F. R. Jackson worked the J. F. Judge hydraulic mine from January 1 to July 1; 22,000 cubic yards of gravel yielded 238 ounces of gold and 33 ounces of silver.

STANISLAUS COUNTY

Knights Ferry district.—Placer Properties Co. operated a dragline dredge on Stanislaus River from January 1 to October 15 and from November 15 to December 31, 1942; two dragline excavators, one with a 6-cubic yard bucket and the other with a 2 ¼-cubic yard bucket, were used.

TRINITY COUNTY

Crow Creek district.—C. L. Kalbaugh operated a suction dredge and tractor on the Thursday No. 1 mine on Crow Creek from May 1 to September 15, 1942; 103 ounces of gold were recovered from 1,000 cubic yards of gravel.

Junction City district.—Junction City Mining Co. operated an electric connected-bucket dredge with 72 9-cubic foot buckets from January 1 to October 28, 1942; 2,077,000 cubic yards of gravel yielded 7,878 ounces of gold and 735 ounces of silver.

Lewiston district.—The Lincoln Gold Dredging Co. operated a dragline dredge, using a dragline excavator with a 2½-cubic yard bucket, on the Costa property on Rush Creek from January 1 to September 12, 1942; 271,744 cubic yards of gravel yielded 1,406 ounces of gold and 95 ounces of silver. Lewiston Placers hydraulicked at the Lewiston Placers mine from January 1 to June 30; 75,000 cubic yards of gravel yielded 188 ounces of gold and 24 ounces of silver.

Weaverville district.—The La Grange Placer Mines, Ltd., hydraulicked 250,000 cubic yards of gravel, which yielded 548 ounces of gold and 52 ounces of silver, at the La Grange Placers mine from January 1 to July 1, 1942. The Dobbin Gulch Dredging Co. operated a dragline dredge, which had a dragline excavator with a 1¼-cubic yard bucket, at the Sunshine and M. A. Brady properties from January 3 to October 19, 1942; at the Sunshine mine 107,300 cubic yards of gravel yielded 348 ounces of gold and 33 ounces of silver.

TULARE COUNTY

White River district.—The Thanksgiving Mining Co. operated the Thanksgiving mine from January 1 to September 1, 1942; 315 tons of ore treated by amalgamation and flotation yielded bullion containing 61 ounces of gold and 22 ounces of silver and concentrates (shipped to a smelter) containing 69 ounces of gold and 28 ounces of silver.

TUOLUMNE COUNTY

Mother Lode district.—Miller & Clemson operated the Eagle-Shawmut mine from January 1 to December 31, 1942; 143,866 tons of ore treated in a 500-ton flotation mill yielded bullion containing 607

Digitized by Google

ounces of gold and 164 ounces of silver and 3, 865 tons of concentrates containing 10,687 ounces of gold, 3,270 ounces of silver, and 7,483 pounds of copper; the concentrates were shipped to a smelter. E. A. Kent operated a dragline dredge with a dragline excavator having a 2¼-cubic yard bucket on the Lyons and Rosasco ranches from January 2 to February 19, 1942; 224 ounces of gold and 15 ounces of silver were recovered from 53,000 cubic yards of gravel at the Lyons ranch, and 308 ounces of gold and 21 ounces of silver were recovered from 52,500 cubic yards of gravel at the Rosasco ranch.

YUBA COUNTY

Smartville district.—The Williams Bar Dredging Co. operated a connected-bucket dredge equipped with 84 6-cubic foot buckets in the bed of Yuba River near Smartville throughout 1942; 2,872,327 cubic yards of gravel yielded 6,354 ounces of gold and 447 ounces of silver.

SUMMARY

The mine production of recoverable silver, copper, and zinc in the Central States decreased in 1942 compared with 1941, but that of lead increased. No output of gold was reported in either year, and the silver produced was derived from base-metal ores. The increase in lead output resulted from capacity operation of the large lead mines in Southeastern Missouri. The decreases in copper and zinc, despite intensified activity in mining, can be attributed to several factors. The developed high- and medium-grade ore reserves were drawn upon heavily in 1940 and 1941 to help meet quickly the expanding requirements of metal for armaments. Operating margins under the controlled and ceiling metal prices prevailing after September 23, 1940, generally were insufficient to meet the increases in operating costs and also provide for extensive new development and prospecting. The full potential effect of the premium-price plan and other measures taken by Federal agencies to get production from marginal and submarginal ores was not reflected in output during the year, owing to the length of time required to reopen and reequip old properties and bring newly found ore bodies to the productive stage. Labor shortages and delay in getting delivery of some materials, such as steel products and electrical equipment, reduced output at some mines.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1938–42

Year	Gold [1]	Silver [2]	Copper [3]	Lead [4]	Zinc [4]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1938	$35.00	[5] $0.646+	$0.098	$0.046	$0.048
1939	35.00	[6] .678+	.104	.047	.062
1940	35.00	[7] .711+	.113	.050	.063
1941	35.00	[7] .711+	.118	.057	.075
1942	35.00	[7] .711+	.121	.067	.093

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.

[2] Treasury buying price for newly mined silver.

[3] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production but excludes value of foreign copper delivered to Metals Reserve Co. for domestic consumption.

[4] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production.

[5] $0.64646464. [6] $0.67878787. [7] $0.71111111.

[1] From placer prospecting.

Silver.—Silver output in the Central States in 1942 comprised 69,106 ounces derived from refining lead bullion, slags, and skimmings recovered from Southeastern Missouri lead ores; 61,674 ounces from Michigan copper ore; and 104 ounces from galena concentrates recovered in milling Illinois zinc-lead ore and fluorspar. Output of silver-bearing lead concentrates from Southeastern Missouri increased in 1942 and their average silver content per ton (about 1.5 ounces) was approximately the same as in other years, but the bulk of the silver was not recovered in the smelter production of chemical (undesilverized) lead and was therefore not included in the production figures for recoverable silver.

Copper.—Copper mines in Michigan yielded 97 percent of the Central States total output of recoverable copper in both 1941 and 1942. The State output was 91,358,000 pounds of refined copper in 1942, and the average recovery per ton of combined rock and sands treated was 20.9 pounds compared with 92,880,000 and 21.7 pounds, respectively, in 1941. The huge war demand for copper and the payment of the Government premium for copper produced in excess of quotas stimulated exploration and development work at Michigan mines. No copper ore was produced in any of the other Central States in 1942. The Missouri production of copper (2,600,000 pounds) was derived from treatment of residues from the smelting of lead concentrates from Southeastern Missouri.

Lead.—Of the 235,229 tons of recoverable lead produced by mines in the Central States in 1942, 197,291 tons (84 percent) came from Southeastern Missouri. The large mines of the St. Joseph Lead Co. in this region contained appreciable reserves of developed ore, which were drawn upon to prevent a shortage of lead for war purposes. The Tri-State region (Kansas, Oklahoma, and Southwestern Missouri) yielded 34,341 tons of lead during the year and Arkansas, Central Missouri, Illinois, Kentucky, and Wisconsin together 3,597 tons. The output from Southeastern Missouri increased 32,949 tons over

Digitized by Google

1941, but the combined output of the other regions decreased 7,082 tons.

Zinc.—Although activity in zinc and zinc-lead mining in the Central States continued to expand during 1942 and many old mines were reopened, the output of recoverable zinc dropped 6 percent below that in 1941; the largest decrease in quantity was 20,901 tons (8 percent) in the Tri-State region, which yielded 92 percent of the total in 1942, 94 percent in 1941, 95 percent in 1940, and 97 percent in 1939. In 1942 Oklahoma contributed 62 percent and Kansas 23 percent of the Tri-State output compared with 64 and 28 percent, respectively, in 1941. A general review of mining and milling in the Tri-State region is given in the pages of this chapter devoted to Southwestern Missouri. Production of zinc in Illinois increased from 9,198 tons in 1941 to 9,389 tons in 1942 and that in Wisconsin from 6,238 to 9,426 tons; in Southeastern and Central Missouri the combined output decreased from 1,100 to 842 tons; in Kentucky the output decreased from 427 to 407 tons and in Arkansas from 206 to 181 tons.

MINE PRODUCTION BY STATES AND REGIONS

Mine production of silver, copper, lead, and zinc in the Central States in 1942, by States, in terms of recovered metals

State	Mines producing	Ore and old tailings (short tons)	Silver

[1] Excludes lead-bearing material mined with fluorspar and from which some lead was recovered as a byproduct of the mining and milling of the fluorspar.

Of the seven lead- and zinc-producing regions in the Central States, three are not limited to a single State. The Central Missouri region yielded a small output, which is combined with that of Southeastern Missouri. The Arbuckle Mountain region of Southern Oklahoma has had no production since 1918. The output by regions in 1942 is given in the following table.

Digitized by Google

Mine production of lead and zinc in the Central States in 1942, by regions

Region	Lead [1]		Zinc [2]		Total value
	Short tons	Value	Short tons	Value	
Concentrates:					
Joplin or Tri-State	44,857	$4,456,782	443,847	$30,905,327	$35,362,109

[1] Includes galena and small quantity of lead carbonate concentrates.
[2] Includes sphalerite and relatively small quantity of zinc carbonate and silicate concentrates.
[3] Includes 180 tons of lead concentrates and 468 tons of zinc concentrates from Central Missouri.
[4] Includes 1,260 tons of zinc-lead carbonate averaging 19.52 percent zinc and 2.46 percent lead.
[5] Region includes Iowa, Northern Illinois, and Wisconsin; no production in Iowa from 1918 to 1942, inclusive.
[6] Includes 141 tons of lead and 179 tons of zinc from Central Missouri.
[7] Includes 28 tons contained in zinc-lead carbonate.
[8] Includes 450 tons recovered in fuming slag from byproduct copper-lead-zinc matte produced in smelting lead concentrates.

Quantity and tenor of copper, lead, and zinc ores, old tailings, etc., produced in some [1] Central States, 1940–42, by States

State	1940		1941		1942	
	Ore, etc.	Metal content [2]	Ore, etc.	Metal content [2]	Ore, etc.	Metal content [2]
	Short tons	*Percent*	*Short tons*	*Percent*	*Short tons*	*Percent*
Kansas	3,153,890	2.40	3,696,247	2.55	3,872,052	1.85

	25,490,145	.....	28,867,251	.....	30,633,547	.....

[1] Only small-scale intermittent mining done in Arkansas from 1918 to 1942; Kentucky and Illinois excluded because part of the metal output (lead and zinc) was a byproduct of fluorspar mining, and the quantity of metal-bearing material hoisted could not be determined.
[2] The percentages represent metal content of the ore insofar as it is recovered in the concentrates. In Michigan the metal so recovered is copper; in other Central States the metals are lead and zinc combined, relative proportions of which are shown in third table of this chapter and in tables of tenor of ore given in sections devoted to the respective States.

MINING AND METALLURGIC INDUSTRY

Most of the ore mined in the Central States is concentrated by the companies producing it, but that mined by some of the large producing companies in the Tri-State and Upper Mississippi Valley regions is sent to custom mills, which also afford an outlet for crude ore produced by individuals and partnerships working small mines or gouging in large mines abandoned by former operators. The bulk of the ore is treated by gravity concentration, supplemented by flotation. Since 1939 a large tonnage of ore has been treated by the differential-density

Digitized by Google

(or sink-and-float) process in the Central mill of the Eagle-Picher Mining & Smelting Co. at Cardin, Okla.; the enriched product resulting from treatment by this process is concentrated further by jigging and flotation. The concentrates produced in the Central States generally have an established market. In 1942 copper concentrates from Michigan were smelted in plants at Hubbell and Houghton, Mich.; lead concentrates from Southeastern Missouri were sent to smelters at Herculaneum, Mo., and Alton, Ill.; and lead concentrates from the Tri-State district went to smelters or pigment plants at Galena and Coffeyville, Kans., Alton and Hillsboro, Ill., Herculaneum, Mo., and Omaha, Nebr. Zinc concentrates from the Tri-State district moved to plants at Bartlesville and Henryetta, Okla.; Coffeyville and Galena, Kans.; Fort Smith and Van Buren, Ark.; Danville, East St. Louis (Fairmont), Hillsboro, and La Salle, Ill.; Donora and Josephtown, Pa.; and Moundsville, W. Va. Most of the lead and zinc concentrates from Wisconsin, Illinois, and other scattered districts in the Central States were shipped to plants that treated the concentrates from the Southeastern Missouri and Tri-State districts. Small tonnages of zinc carbonate from Arkansas and Missouri were shipped to chemical plants at Collinsville, Ill., and Newcastle, Pa.

REVIEW BY STATES

ARKANSAS

The small output of lead and zinc in Arkansas in 1942 came from 33 mines and prospects in Boone, Izard, Lawrence, Marion, Newton, and Searcy Counties. None of the mines was a steady producer, and only 4 shipped as much as a carload of concentrates. The total shipments comprised 485 tons of carbonate and mixed carbonate, silicate, and sulfide averaging 39.50 percent zinc, 33 tons of sulfides averaging 57.10 percent zinc, and 3 tons of lead concentrates averaging 63.33 percent lead. Most of the carbonate produced from January to October was sold in small lots to the Manda Industrial Corporation at Harrison, which shipped it in carlots to the Chemical & Pigment Co. at Collinsville, Ill. The rest of the zinc concentrates were shipped to smelters at Fort Smith and Van Buren, Ark. Small tonnages of concentrates were produced in mills at the Gloria-Alma-Jackpot group near Zinc, Boone County; the Edith, Leader Hollow, and McIntosh near Rush, Marion County; the Bald Hill, Newton County; and the Excelsior and Lone Star, Searcy County. The Silver Hollow group near Rush and the Big Hurricane in Searcy County were reopened for examination through preliminary R. F. C. loans. The Bureau of Mines did 3,368 feet of diamond drilling in the Rush Creek district to explore strata below mining done in the past.

ILLINOIS

Northern Illinois (*see section on Wisconsin for output data*).—All the lead and zinc ores shipped from mines in Northern Illinois in 1942 were sold to the Vinegar Hill Zinc Co. custom mill near Cuba City, Wis. Gill Bros. continued to work the old Hughlet and Gray mine near the Illinois-Wisconsin State line and also worked the adjacent North Unity from July through December and the South Unity throughout October. The Hughlet and Gray was shut down February

Digitized by Google

4, 1943, but the North Unity, on which a 132-foot shaft was sunk in 1942, continued producing good ore. Individuals shipped a few truckloads of ore from Scales Mound and Galena. The Bureau of Mines approved an exploratory drilling project on the Gray property south of Galena and had three churn drills running under contract early in 1943.

Southern Illinois.—From 1939 through 1942 the zinc-lead fluorspar mines of the Mahoning Mining Co. near Cave in Rock, Hardin County, contributed most of the zinc and lead output from Southern Illinois. In 1942 the company operated the W. L. Davis-Deardorff, Green No. 1, and Anna L. Davis mines. The ore is composed chiefly of fluorspar, sphalerite, and galena, which are recovered as separate products in the company 200-ton selective flotation mill at Rosiclare. The fluorspar concentrates produced in 1942 were mostly of acid grade; the sphalerite averaged 62.87 percent zinc, and the galena 63.88 percent lead. A small part of the mill feed was custom ore from other properties in Southern Illinois and Kentucky, mostly fluorspar mines yielding zinc and lead as byproducts. During the year the company sank a 363-foot shaft on the Green No. 1 mine and began sinking another shaft on the Green No. 2; at the end of the year it had six drills at work in a greater effort to discover and extend ore bodies and was installing additional machinery to expand the capacity of the mill. Hillside Fluor Spar Mines continued to ship byproduct lead concentrates. The total output of lead concentrates in Southern Illinois in 1942 was 3,566 tons averaging 63.83 percent lead and about 5.14 ounces of silver to the ton, and that of zinc concentrates was 13,590 tons averaging 62.87 percent zinc. Production (in terms of recovered metals) amounted to 2,211 tons of lead, 104 ounces of silver, and 7,689 tons of zinc, compared with 2,256 tons of lead, 20,340 ounces of silver, and 7,480 tons of zinc in 1941.

KANSAS

The Kansas lead and zinc mines are in the Tri-State (Joplin) mining region, embracing parts of Cherokee County, Kans., and Ottawa County, Okla., and about 12 counties in Southwestern Missouri. General details of the Tri-State mining industry are given in following pages devoted to Southwestern Missouri.

The total output of zinc from Kansas ores and old tailings decreased 22 percent and lead 35 percent in 1942 from 1941. The Baxter Springs-Blue Mound-Treece area extending northward from the Oklahoma-Kansas State line has been the principal producing area since 1918; it yielded 96,856 tons of zinc concentrates and 12,183 tons of lead concentrates in 1942 compared with 122,582 and 18,835 tons, respectively, in 1941 (revised figures), and an annual average of 122,024 and 18,973 tons from 1918 through 1940. In 1942 the output of both zinc and lead from the Eagle-Picher Mining & Smelting Co. Westside-Barr and Webber mines was less than in 1941, and the total output of the Big John, Black Eagle, Chubb, Mid-Continent, Wilbur, and Robob mines shipping to the Central mill at Cardin, Okla., decreased. The Webber mill was closed in October, and the ore from the Webber lease was diverted to the Central mill. Two shafts on the lease north and northwest, respectively, of the Webber mill shaft were reopened, and spur tracks connecting them with the railroad to the Central mill were built. A shaft on the Foley land was reopened

Digitized by Google

to facilitate mining of the Westside ore, and the old Westside mill shaft was being converted for double-skip hoisting in conjunction with the erection of a 1,000-ton hopper. Other new Eagle-Picher operations in Kansas included reopening of the Lucky Jew Parmenter and Velie Leopard properties. In November the company also began preparing to reopen the Paxson mine and 2,400-ton mill as agent for the Metals Reserve Co. This mine began producing in April 1943.

The 1,800-ton Ballard central mill of the St. Louis Smelting & Refining Co. was operated at approximate capacity throughout 1942 on company ore from the Ballard, Bailey, Clark, English "O", Keith, Shanks, Slaughter, and Walter H. mines; the output of zinc concentrates was less than in 1941, but that of lead concentrates was approximately the same in both years. The Bilharz Mining Co. operated the Bilharz-Brewster mine throughout 1942, treating the ore in the company mill which also handled crude ore from the L. D. Brewster and Huttig mines in Oklahoma from January to July. The Madison mill was run steadily on ores from the Peru-Banning group and Craig and Brugger leases. The Wade custom mill treated 20,817 tons of mine dirt from the Discard, Commonwealth, and other small mines in Kansas and Oklahoma. From September through December the Mineral Products Co. shipped crude ore from a shaft on the Swalley property to the Mission mill in Oklahoma. The Pilot mill was shut down in March and remained idle the rest of the year. The Oldham Mining Co. shipped ore to custom mills. The Dines Mining Co. continued to run its mill on company and custom ores, mostly from the Southern, Harris, and Hartley No. 1 mines. The Beck No. 3 mill at Baxter Springs was reconditioned to treat company and custom ores and was put in operation in January 1943; part of the ore treated came from the McArthur mine, on which two shafts were sunk in 1942. The Muncie mill of the Federal Mining & Smelting Co. was closed in April, and the ore from the Muncie-Tar Creek-Semple group was then sent to the company Gordon central mill in Oklahoma, which also treated other Kansas ore from the Federal Jarrett mine. The north shaft on the Muncie was reopened and reequipped for additional development. The Muncie mill and the remaining part of the old Jarrett mill were dismantled and salvaged. The Harris Mining Co. continued to work the Robinson mine and in October began mining ore from a new shaft on the Silver Fox lease. The ore from these two mines and that from the leased Evans-Wallower No. 24 was concentrated in the Youngman mill. The Opperman mine, operated by the Lula Bell Mining Co., was closed in August. The New Blue Mound Mining Co. operated one section of its mill on crude ore from the Blue Mound mine, and the Worley Mining Co. operated the other section on new tailings from the Blue Mound ore and old tailings hauled from scattered piles in the vicinity. The Captain and Early Bird tailing mills were run steadily, and their output of zinc concentrates was larger than in 1941.

The Kansas part of the Waco district yielded 5,113 tons of zinc concentrates and 5 tons of galena in 1942 compared with 8,361 and 15 tons, respectively, in 1941. The St. Louis Smelting & Refining Co. operated its No. 9 mill (capacity 800 tons in 16 hours) throughout 1942. More than half the ore treated came from the company Olsen and High Five leases in the Missouri part of the Waco district; the

Digitized by Google

rest came from the company Grasselli and J. M. Bennett leases, the Stotts City Mining Co. J. M. Bennett lease, and the Beck Mining Co. Hurlbut lease. The F. W. Evans mill treated ore from the O'Neill land (partly in Kansas and partly in Missouri), the St. Louis Smelting & Refining Co. land, and the Blue Rock mine in Missouri. In the Galena area, formerly (1876–1917) the principal zinc- and lead-producing area in Kansas, the Eagle-Picher Mining & Smelting Co. continued churn drilling, sank two new shafts and reopened several old shafts, and did underground development work and pumping. Ore shipments to the company Bird Dog mill in Oklahoma began in March 1943. The Galena Mining Co. shipped crude ore from the Southside mine to the Central mill.

Mine shipments of lead and zinc in Kansas, 1938–42

Year	Mines producing	Lead concentrates		Zinc concentrates		Metal content[1]			
						Lead		Zinc	
		Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1938	31	19,909	$1,023,851	133,546	$4,132,248	15,239	$1,401,988	73,024	$7,010,304
1939	30	17,845	1,010,106	126,235	4,300,365	13,697	1,287,518	68,971	7,172,984

1942	81	12,253	1,167,302	103,247	6,926,745	9,419	1,262,146	55,874	10,392,564

[1] In calculating metal content of the ores from assays allowance has been made for smelting losses of both lead and zinc. In comparing the value of ore and metal it should be borne in mind that the value given for the ore is that actually received by the producer, whereas the value of the lead and zinc is calculated from the average price for all grades.

Tenor of lead and zinc ore and old tailings milled and concentrates produced in Kansas, 1941–42

	1941		1942	
	Crude ore	Old tailings	Crude ore	Old tailings
Total ore and old tailings milled.....short tons..	2,446,207	1,250,040	2,170,121	1,701,981
Total concentrates produced:				
Galena.....do....	18,886	2	12,253	----------
Sphalerite.....do....	123,000	8,406	92,540	10,707
Ratio of concentrates to ore, etc.:				
Lead.....percent..	0.77	----------	0.56	----------
Zinc.....do....	5.03	0.67	4.26	0.63
Metal content of ore, etc.:[1]				
Lead.....do....	.61	----------	.44	----------
Zinc.....do....	3.04	.40	2.57	.36
Average lead content of galena concentrates.....do....	78.54	50.0	78.44	----------
Average zinc content of sphalerite concentrates....do....	60.48	58.9	60.38	57.96
Average value per ton:				
Galena concentrates	$66.93	$56.00	$85.27	----------
Sphalerite concentrates	50.32	48.38	65.55	$80.42

[1] Figures represent metal content of the crude ore (or "dirt") only insofar as it is recovered in the concentrates; data on tailing losses not available.

KENTUCKY

Part of the Kentucky output of zinc and most of the lead in 1942 were byproducts of fluorspar mining. The United States Coal & Coke Co. Fluorspar Division, operating the Lafayette mine near Mexico, was the principal shipper of byproduct zinc concentrates and also shipped lead concentrates. The largest shipper of lead con-

Digitized by Google

centrates was the Kentucky Fluor Spar Co., which recovered the concentrates in milling fluorspar from the Babb mine. The Cumberland Fluorspar Co., Delhi Foundry Sand Co., and Summers Fluorspar Mine shipped zinc-lead fluorspar ore to the Mahoning mill at Rosiclare, Ill. The Cumberland Fluorspar Co. also shipped 530 tons of carbonate ore averaging 30.62 percent zinc to oxide plants. During November and December the Eagle-Picher Mining & Smelting Co. shipped 1,220 tons of crude zinc-lead sulfide ore from its Nunn mine 6 miles east of Marion to the company Central mill at Cardin, Okla. The total State output of recoverable zinc was 407 tons and that of lead 335 tons compared with 427 and 282 tons, respectively, in 1941. The Twin Valley Mining Co. continued developing the Gratz mine in Owen County and installed additional equipment in the mill, increasing its capacity (formerly 50 tons daily) to 100 tons. Mining and milling of ore were begun in February 1943.

MICHIGAN

Although the output of refined copper in Michigan decreased 2 percent in 1942 from 1941, there was a material expansion in 1942 in the scope of mining and development operations by the mining companies. Special arrangements with Federal procurement agencies in the latter part of 1941, whereby the copper produced from certain "high-cost" mines would be paid for on a cost-plus basis, and the premium-price plan placed in effect in February 1942 enabled the companies to make preparations to mine and mill copper-bearing rock not commercial under the ceiling copper price of 12 cents a pound. The average grade of the crude ore mined was 10 percent lower than in 1941, and that of old tailings (sands) treated at reclamation plants was slightly lower. The total crude ore treated increased from 1,741,961 tons in 1941 to 1,952,781 tons in 1942; tailings decreased from 2,540,487 to 2,409,859 tons. The tailings yielded 34 percent of the total copper in 1942 and 36 percent in 1941.

The concentrate ("mineral") produced at mills in Michigan in 1942 was smelted at plants of the Calumet and Hecla Consolidated Copper Co. at Hubbell and the Copper Range Co. at Houghton. Some of the copper bullion was cast into anodes and shipped to the electrolytic refinery at Laurel Hill, N. Y., where silver was recovered. Silver was also recovered by hand-picking at the mine and from some of the concentrates.

Mine production of silver and copper in Michigan, 1938–42 [1]

Year	Silver (fine ounces)	Copper [2]			Concentrate ("mineral") [3]		Ore ("rock") (short tons) [4]
		Pounds	Yield		Pounds	Yield (percent copper)	
			Pounds per ton of ore ("rock")	Percent			
1938	93,624	93,486,000	24.9	1.24	144,964,890	64.5	3,757,705
1939	101,878	87,970,000	19.1	.96	136,771,339	64.3	4,603,751
1940	88,657	90,396,000	20.4	1.02	138,451,495	65.3	4,438,219
1941	60,796	92,880,000	21.7	1.08	141,100,268	65.8	4,282,448

Value of silver and copper produced in Michigan mines, 1938–42

Year	Silver	Copper		Total	Year	Silver	Copper		Total
		Total	Per ton of ore ("rock") and sands				Total	Per ton of ore ("rock") and sands	
1938	$60,531	$9,161,628	$2.44	$9,222,159	1941	$43,233	$10,959,840	$2.56	$11,003,073
1939	69,154	9,148,880	1.99	9,218,034	1942	43,857	11,054,318	2.53	11,098,175
1940	63,045	10,214,748	2.30	10,277,793					

The Calumet and Hecla Consolidated Copper Co. continued to be the largest producer of copper in Michigan. After June 1, 1942, when the company purchased all the physical assets of the Wolverine Tube Co. (manufacturer of seamless nonferrous tube) at Detroit, the mining, smelting, and other company operations in Northern Michigan were operated as the Calumet Division, and the newly acquired enterprise became the Wolverine Tube Division. The producing company mines in 1942 were the Ahmeek, Peninsula, Douglass, and No. 4 North Kearsarge groups. The ore from all four groups was treated in the 6,800-ton Ahmeek stamp mill by gravity concentration followed by flotation of the fines. The details of operations at the mines that follow were extracted from the annual company report to stockholders. Operations at the Ahmeek mine were confined largely to stoping. Exploration of the Peninsula area was continued throughout the year. A heavy program of dead work, consisting of the extension of No. 4 shaft, reopening of three old levels, and unwatering old Seneca workings, resulted in high costs for the copper produced. No important new ore shoots were discovered, but the extension of two known ore shoots was determined. At the Douglass group a total of 6,228 feet of openings was driven from No. 2 and No. 3 Ahmeek shafts. A large portion of the openings was in low-grade vein, but a reasonable percentage was in ground of probable commercial value. The No. 4 North Kearsarge mine was reopened and operated under a contract with the Metals Reserve Co. During February and March the surface plant and underground openings were rehabilitated; production started in April at a moderate rate and increased gradually throughout the year. On the Iroquois property a surface plant was constructed, an exploratory inclined shaft was sunk to a depth of about 700 feet, and 196 feet of drifting was done at the 600-foot level. At the Central property underground workings were unwatered, the surface plant was repaired, diamond drilling was done, the shaft was sunk 128 feet below the 200-foot level, and crosscutting to the mineralized area was begun.

Both the Lake Linden and the Tamarack dredges operated in the older, richer parts of the respective deposits adjacent to the original shore lines. At Lake Linden the conglomerate tailings above the water line will have disappeared before the end of the coming summer, and operations thereafter will be spotty and irregular until reserves are exhausted. The profitable life of this asset is short. At Tamarack there is some promise of an extended life on amygdaloid tailings if a suitable price can be obtained for the copper produced.

Copper output from the Champion and Globe mines of the Copper Range Co. increased in 1942. The ore from both mines was treated

Digitized by Google

in the company mill at Freda. Copper recovered from 355,630 tons of mine ore and 223,859 tons of sands treated in the tailings-recovery plant totaled 18,441,607 pounds. The average yield of fine copper per ton of mine rock was 49.97 pounds compared with 52.38 pounds in 1941. Mine workings include two 70° shafts about 5,000 feet deep and one subshaft about 400 feet deep. Development work done during the year totaled 198 feet of shaft, 12,086 feet of drifts and crosscuts, and 12,571 feet of diamond drilling. The concentrates were smelted in the company smelter, which also handled custom concentrates from the mills of the Isle Royale Copper Co. and the Quincy Mining Co.

The Isle Royale Copper Co. mine and 2,000-ton stamp mill were run continuously in 1942. Crude ore produced totaled 315,142 tons compared with 316,598 in 1941. The yield of fine copper per ton of rock averaged 20.16 pounds in 1942 and 21.223 in 1941. The 1942 annual company report to stockholders stated that mining costs were gradually increasing and that notice had been received in February 1943 of an increase in wages awarded by the Nonferrous Metals Commission; the notice indicated that some increase in the copper price would be necessary to enable the company to pay the wage increase.

The Quincy Mining Co. operated its mine and mill continuously in 1942. Both the tonnage of rock treated and the yield of copper per ton were slightly lower than in 1941. In 1942 the company obtained a loan of $1,150,000 from the Metals Reserve Co. to be expended in constructing a 4,000-ton plant for re-treating the Quincy Mining Co. tailing deposit at Mason, on Torch Lake. The loan is to be retired by payment of 4 cents per pound of copper produced. The plant will be constructed by the Calumet and Hecla Consolidated Copper Co. which will furnish much of the machinery from dismantled structures no longer needed by that company. After completion, the plant will be operated by the Quincy Mining Co. All the copper produced will be sold to the Metals Reserve Co. for 17 cents a pound.

From January through December 1942 Arcadian Mines (incorporated May 2, 1942) drove 1,250 feet of development drifts and 150 feet of crosscuts on the company property on the south side of Ripley Hill. The Ripley adit, through which the property is being developed, was 2,050 feet long at the end of the year. About 250 tons of ore removed in drifting were stored for a mill test, and nearly a ton of native ("mass") copper was sent to the Copper Range smelter.

MISSOURI

In 1942 Missouri maintained by a wide margin the rank it has held for 35 years as the chief lead-producing State. Under the stimulus of heavy demand and higher prices brought on by the war, the output of zinc increased 73 percent in 1941 over 1940 and 66 percent in 1942 over 1941. Lead production increased 20 percent in 1942 over 1941. The lead comes largely from the Southeastern Missouri region and the zinc mostly from Southwestern Missouri. In 1942 silver, copper, and zinc were recovered in relatively small quantities as byproducts in smelting and refining lead concentrates from Southeastern Missouri. The Central district of Missouri produced 141 tons of recoverable lead and 179 tons of zinc in 1942; these figures are combined with those of Southeastern Missouri in the table that follows.

Digitized by Google

Mine production of lead and zinc in Southeastern and Central Missouri, 1938–42

Year	Lead concentrates (galena)		Zinc concentrates (sphalerite)		Metal content [1]			
					Lead		Zinc	
	Short tons	Value [2]	Short tons	Value	Short tons	Value	Short tons	Value
1938	163,500	$9,040,593			118,870	$10,936,040		
1939	210,526	12,339,360			153,522	14,431,068		
1940	232,871	14,269,600	[3] 815	$20,090	169,908	16,990,800	233	$29,358

1942	277,255	19,426,540	[5] 1,739	41,913	197,432	26,455,888	[6] 842	156,612

[1] In calculating metal content of the ores from assays allowance has been made for smelting losses of both lead and zinc. In comparing the values of ore and metal it should be borne in mind that the value given for the ore is that actually received by the producer, whereas the value of the lead and zinc is calculated from the average price for all grades.

[2] Values given are to a certain extent arbitrary, as part of the lead concentrates are smelted by the producer.

[3] Includes 500 tons of zinc carbonate ore containing 106 tons of recoverable zinc.

[4] Includes 4,720 tons of zinc-lead carbonate concentrates containing 893 tons of recoverable zinc and 172 tons of lead.

[5] Includes 1,271 tons of zinc and zinc-lead carbonate concentrates containing 213 tons of recoverable zinc and 28 tons of lead.

[6] Includes 450 tons recovered in fuming slag from byproduct copper-lead-zinc matte produced in smelting lead concentrates.

[1] Figures represent metal content of the crude ore (or "dirt") only insofar as it is recovered in the concentrates; data on tailing losses not available.

Southeastern and Central Missouri.—The disseminated-lead district of Southeastern Missouri yielded 197,291 tons of recoverable lead in 1942—an increase of 32,949 tons (20 percent) over 1941. The bulk of production in 1942, as in the past, came from St. Francois County, where the St. Joseph Lead Co. operated continuously its four groups of mines and four mills, comprising the Bonne Terre, Leadwood, Desloge, and Federal Divisions. The mines were operated two 8-hour shifts per working day and the mills three 8-hour shifts, and all worked 6 days a week. Ore hoisted per day averaged 21,100 tons, which kept the mills operating at capacity. One ore-hoisting shaft is at each mill; in addition, there were 11 operating shafts equipped for handling men, supplies, and poor rock. The average depth of the four ore-hoisting shafts is 440 feet. The ore occurs in extensive, flat-lying deposits in limestone and is mined from open stopes supported by pillars. Electric-powered mechanical loaders and locomotives are used for loading and underground haulage. Mine development and drilling done in 1942—77,143 feet of drifts, a 716-foot raise, 9,564 feet of churn drilling, and 2,305,272 feet of diamond drilling—were nearly double the total in 1941. New equipment purchased included 6 diamond core drills, 12 underground mechanical loaders, 100 mine cars, and 24 underground trolley locomotives. The annual company report to stockholders for 1942 stated that although the mines were still being worked beyond their economic capacity the development work during the year was very satisfactory, and the tonnage of proved ore was greater than it had ever been. In Madison County production of lead from the Mine La Motte mine of the Mine La Motte Corporation (50-percent owned by the St. Joseph Lead Co.) also increased. The 1,000-ton mill was enlarged during the latter part of 1942 to provide 500 tons additional daily capacity to treat the chat tailings from old operations. Mine development and drill prospecting done totaled 3,451 feet of drifts and 41,026 feet of churn

Digitized by Google

drilling. The Fredericktown Lead Co., which had purchased the mining leases on the Catherine and Fleming tracts and the 400-ton Clark and Hallock mill, installed a new Diesel power plant, surface buildings, and mining equipment and in March began treating ore from the reopened Catherine mine. During the rest of the year 96,763 tons of ore were treated, yielding 2,470 tons of 76-percent lead concentrates. Of the 277,075 tons of lead concentrates made in 1942 in Southeastern Missouri, about 129,560 tons were flotation concentrates. The St. Louis Smelting & Refining Co. carried on prospect drilling and mine-development work at its own property and the adjoining leased property of the Missouri Cobalt Co. at Fredericktown; the commercial metals in the ore are lead, copper, nickel, and cobalt. The ore was tested in the Bureau of Mines laboratory at Rolla to develop a suitable treatment process.

The zinc ore and concentrates shipped from Southeastern Missouri in 1942 were carbonates, mostly from old dumps on the Valle Mining Co. properties in Jefferson and St. Francois Counties and the Frumet mine on the Tausig estate west of DeSoto. Shipments totaled 1,271 tons, averaging 19.76 percent zinc and 2.44 percent lead.

In Central Missouri the Wemhaner Mining Corporation continued to mine zinc, lead, and coal from its leased open-pit mine on the Monarch Coal & Mineral Co. land in Moniteau County. In treatment, the coal and some waste are removed by screens and coal jigs, and the ore rock is then concentrated further in ore jigs. Otis and E. M. Sullens worked the Lowery mine near Enon on a small scale and shipped 150 tons of galena averaging 80 percent lead. A 2-ton lot of lead ore was shipped from Lynn Creek.

Southwestern Missouri.—The method of marketing the mine output in the Tri-State or Joplin lead and zinc region (Southwestern Missouri, Kansas, and Oklahoma) is explained in the reports of this series for 1940 and 1941.

The total value given in this report for all concentrates produced in the Tri-State region is based upon actual receipts by the sellers and not upon quoted prices. Under the ceiling price of 8.25 cents a pound for slab zinc at East St. Louis, the quoted price for zinc concentrates at Joplin remained at $55.28 a ton throughout 1942. The quoted price for galena opened in January at $68.64 a ton on a metal contract basis; on January 13 it was raised to $76.75, which held until March 28 when the price was reduced slightly to $76.54; it remained at that level the rest of the year.

Effective February 1, 1942, the Metals Reserve Co. paid premiums of $28.05 a ton for 60-percent zinc concentrates and $39.60 for 80-percent galena for production from individual mines in excess of quotas fixed jointly by the War Production Board and the Office of Price Administration. On December 1 the premiums were increased slightly to $29.70 a ton for zinc concentrates and $41.80 for galena following a revision of the formula used in determining the recoverable-metal content of the concentrates; the recovery factor for zinc was raised from 85 to 90 percent and that for lead from 90 to 95 percent.

Early in 1943 the scope of the premium-payment program was broadened to afford an additional premium for lead (called "B"-level quota) and an additional premium or premiums for zinc (called "B" and "C" level) at operations where such additional premiums were considered essential to insure maximum necessary mine pro-

Digitized by Google

duction. The premium payments on the "B"-level quota were twice those on the original or "A" level, and the payment on the "C" level (zinc only) was three times that on the "A" level. The maximum combined commercial price and premiums obtainable for standard-grade zinc concentrates was therefore $144.38 a ton and for lead concentrates $160.14.

All Government premium payments for zinc and lead produced from restricted Indian lands in 1942 were subject to royalties, at rates (usually 10 percent) specified in the leases, for money received from sales at market prices. Lessees on other lands with one or two exceptions also paid part of the premium moneys received as royalty. In April 1943 the Office of Price Administration issued Maximum Price Regulation 356 freezing royalties on April 1 at rates in effect December 31, 1942. Under this regulation, "B"- and "C"-level premiums are not subject to royalties.

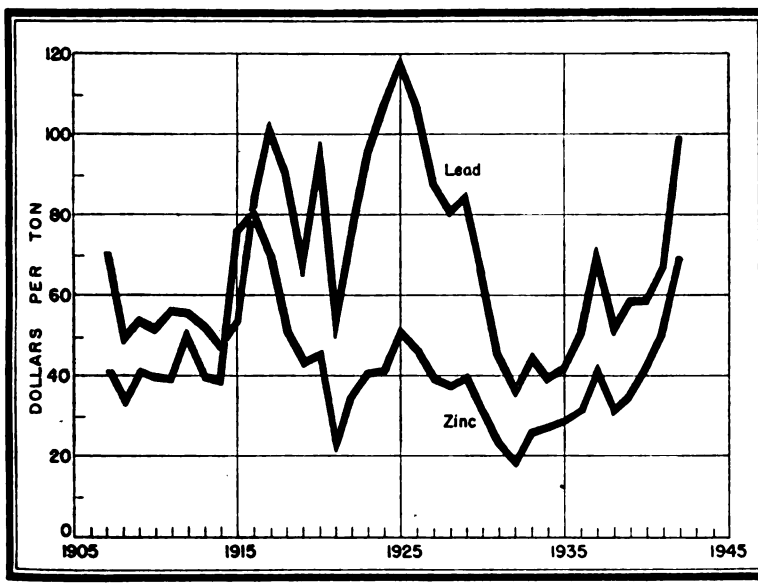

FIGURE 1.—Average prices received by sellers per ton of concentrates in the Tri-State district, 1907–42.

Local mining companies did much prospect drilling and other exploration and development work in 1942. The total number of drill rigs in operation rose from 67 on March 31 to 99 on June 30 and 100 on November 1. About 21 new shafts (averaging 190 feet deep) were sunk during the year, and at least 43 old shafts were reopened; reopenings, however, were partly offset by closings. Progress was made in mechanizing underground loading, and by the end of the year about 50 drags and more than 100 other types of mechanical loaders were being used in the district. Labor shortages, which became acute for some operators during the summer and early fall, were somewhat ameliorated later in the year. In general, established mines and mills were able to obtain needed supplies and replacement equipment under assigned priority ratings, although there was delay at times in getting

Digitized by Google

delivery of steel products, lumber, and electrical equipment. The Reconstruction Finance Corporation granted loans for development and mining on about 15 Tri-State properties, and the Bureau of Mines investigated 34 properties and did churn drilling on the Townsite mine at Cardin, Okla.

Production of zinc in Southwestern Missouri again increased in 1942 and was the highest annual since 1918. The Oronogo Circle open-pit mine at Oronogo continued to be the largest producer. The ore is mined by the Oronogo Mutual Mining Co. and milled by the Eagle-Picher Mining & Smelting Co. Under a program undertaken in July to expand production, the rate of ore extraction was stepped up beyond the capacity of the mill on the property, and part of the crude ore was diverted to other Eagle-Picher mills in Oklahoma and Missouri. The rock milled totaled 287,680 tons; in addition, 295,520 tons of waste rock and overburden were removed from the pit, which was 230 feet deep at the end of 1942. The Fenix & Martin Mining Co. continued to operate the La Tosca mine and 200-ton mill, and Fenix & Sons shipped crude ore from a shaft on the Oronogo Mutual property to the Central mill in Oklahoma. Kansas Explorations, Inc., operated its Snapp mine and 600-ton mill near Oronogo throughout the year; the company also reopened the old A. W. C. property near Joplin and equipped it with a 1,000-ton mill, which was put in operation in October. The Eagle-Picher mines served by the Navy Bean mill near Wentworth made a large output in 1942. The Federal Mining & Smelting Co. operated six shafts (average depth 170 feet) on its Granby-American property, treating the ore in the company 1,200-ton mill; the company also developed its Granby-Davis lease, which began producing in September, and nearly completed a large mill at its Duenweg mine. The new mill and the Duenweg mine were placed in operation about April 1, 1943. The American Zinc, Lead & Smelting Co. drilled out a good ore body on the Henckle and Smith lands near Duenweg in 1942 and began developing it by sinking three shafts; the mine was put in operation late in March 1943, and the ore produced was treated on a contract basis in the new Federal mill at Duenweg. The company also struck good ore at Aurora while drilling on the McLain-Jones land and began constructing a mill on the property in March 1943.

The principal producer near Joplin was the Missouri Mining Co. 1,200-ton tailing mill at Chitwood. The High Grade Mining Co. reopened its mine and mill in May and operated until November; the property was then idle until March 1943, when it was put in operation by the Southside Mining Co. The Northside Mining Co., which had its ore milled in the High Grade mill in 1942, built a mill on the Northside property and began milling in January 1943. The St. Louis Mining & Milling Co. operated its custom mill at Thoms Station steadily, affording milling facilities for small mines operating nearby. At Waco the St. Louis Smelting & Refining Co. worked its High Five and Olsen leased mines and sent the ore to the company No. 9 mill across the State line in Kansas. F. W. Evans Mines operated the O'Neill and Blue Rock mines and treated the ore in the company mill in Kansas. C. C. Playter ran his mill (capacity, 12½ tons an hour) continuously on ore from his Reynolds lease at Waco and other ores from small mines near Carl Junction, Joplin, Neck City, and Pleasant Valley and from Galena, Kans. At Webb City the Sciota Milling Co. mill ran steadily on tailings from the Connor Investment Co. land and other properties. Early in 1943 Cooley Bros. began stripping operations with draglines and bulldozers on the F. W. Evans land in Sucker Flat. At Stotts City the Capital Mining Co. continued to operate its Capital mine and in July purchased the adjacent Stotts

Digitized by Google

City Mining Co. property; the ore from both mines was treated in the Capital mill. The Harris Mining Co. mill north of Aurora was run intermittently. Near Ozark, Christian County, the Mary Arnold mine and mill were operated from January through October, and the Monark Mining Co. property was under development and made a small output early in the year. The Wentworth Mining & Milling Co. operated the Kline mine and mill after July. The Southwest Mining Co. began developing its property at Stark City and nearly completed a 250-ton mill before the year ended. Eleven small mills in the Alba-Neck City, Carthage, Duenweg, Granby, Joplin, and Webb City areas produced some concentrates in 1942, mostly from tailings. Zinc carbonate and silicate shipped from scattered mines and dumps in Southwestern Missouri in 1942 (including low-grade zinc-lead concentrates from Granby dump material treated in the Goade mill) totaled 1,510 tons averaging 23.25 percent zinc and 3.58 percent lead.

OKLAHOMA

General details of mining and milling in the Tri-State region—which includes northeastern Oklahoma—are given in the preceding pages on Southwestern Missouri. Although Oklahoma continued to yield much the largest part of the total Tri-State production of both zinc and lead, the State output of recoverable lead decreased 9 percent and zinc 12 percent in 1942 from 1941. The total value of the zinc and lead concentrates, however, increased 26 percent owing to the advance in average market prices and the payment by the Government of premiums for over-quota production. About 141 mines produced during the year and 26 mills were operating at the end of the year compared with 120 and 27, respectively, in 1941.

[1] In calculating metal content of the ores from assays allowance has been made for smelting losses of both lead and zinc. In comparing the values of ore and metal it should be borne in mind that the value given for the ore is that actually received by the producer, whereas the value of the lead and zinc is calculated from the average price for all grades.

[1] Figures represent metal content of the crude ore (or "dirt") only insofar as it is recovered in the concentrates; data on tailing losses not available.

In 1942 the Eagle-Picher Mining & Smelting Co. was again by far the largest producer of both lead and zinc in Oklahoma and in the Tri-State region. The company 13,000-ton Central mill at Cardin treated a total of 3,599,087 rock tons of company and custom ore, of which 2,905,220 tons (81 percent) came from Oklahoma mines, compared with 3,311,144 tons in 1941, of which 2,711,212 tons (82 percent) came from Oklahoma. The concentrating equipment of the mill includes, besides the usual jigs, flotation machines, and tables, a large primary heavy-density (or sink-and-float) cone unit and a smaller secondary cone which provide preliminary stages of concentration at coarse sizes for a large portion of the mill feed. Company-operated mines in Oklahoma shipping to the mill in 1942 were the Blue Goose Nos. 1, 2, and 3, Crawford, Crystal No. 1, Crystal-Central, Eagle-Picher Gordon Nos. 1 and 2, Grace Walker Nos. 1 and 2, Goodeagle Nos. 1 and 3, Hum-bah-wat-tah Nos. 1, 2, and 3 (includes Jaybird), John Beaver Nos. 1 and 2, Little Greenback, Mehunka, Netta, Niday No. 1, See Sah, Southside Nos. 1 and 2, Stanley, and Wesah Greenback. The Crawford, Goodeagle Nos. 1 and 3, Mehunka, Niday No. 1, Netta, and Southside Nos. 1 and 2 (closed in May 1941) were reopened during the year. The Crawford and Gordon No. 1 were shut down in October and July, respectively, owing to exhaustion of ore; the John Beaver No. 1 was shut down in May because the property was too low-grade to work. New shafts were sunk on the Beck Robinson, Goodeagle No. 3, and Niday No. 1 properties. The Eagle-Picher 2,400-ton Bird Dog mill was not run in 1942 but was reopened in March 1943 and began treating ores from Oronogo, Mo., and Galena, Kans.

The principal shippers of Oklahoma custom ore to the Central mill in 1942 were the American Development Co. (Hunt mine), Baird Mining Co. (American-Douthat), Cameron & Henderson (Admiralty), Cortez-Childress (Jeff City), Davis-Big Chief Mining Co. (Eudora-Whitebird, Imbeau, and Skelton), F. W. Evans (Shorthorn, Tom L.), Lula Bell Mining Co. (Anna Beaver), Mahuska Mining Co. (Acme),

Digitized by Google

M. & M. Mining Co. (LaSalle, Piokee, Swift, Whitebird), and Mutual Mining & Development Co. (Slim Jim).

The Federal Mining & Smelting Co. operated its 1,700-ton Gordon central mill throughout 1942 on company ore from the Gordon, Howe, Lucky Bill, Lucky Syndicate, and Quapaw-Davenport mines in Oklahoma and the Federal Jarrett and Muncie groups in Kansas; the mill, built in 1937, operated until March 7, 1943, when it was destroyed by fire. The mines served by the mill were closed, and no announcement was made immediately regarding their future operation. The Rialto Mining Corporation operated its No. 3 mine and mill continuously; the No. 2 mill, handling tailings since 1938, was remodeled early in 1942 to treat mine ore from the reopened No. 2 mine and was run as a mine mill until it burned on February 12, 1943. The corporation reopened its No. 4 mine (old L. & G.) about September 1942 and concentrated the ore in the No. 2 mill. Soon after this mill burned the No. 3 mill began operating three shifts daily and handled ore from other company mines in addition to that from the No. 3 mine.

The Jane E. Mining Co. reopened its Scott mill January 1, 1942, and resumed the milling of Scott mine ore; the crude ore mined from this property in 1941 was sent to the Central mill. Development work done at the Scott mine in 1942 included sinking a 275-foot shaft and 1,945 feet of churn drilling. Evans-Wallower Zinc, Inc., ran its No. 7 mine and mill continuously in 1942, and its No. 4 mine and mill from January 1 through February 26 when operations were suspended pending conversion of the No. 4 mill into a tailing plant to re-treat old tailings from the old Golden Rod property on which the company had obtained a lease. Milling of the tailings and some mine ore was begun in June and continued the rest of the year. The Weidman Mining Co. ran the Woodchuck and Townsite mines, treating the ore, as well as some custom ore, in the Woodchuck mill. The United Zinc Smelting Corporation continued to operate its Royal mine and mill; the mill also handled custom ore, mostly from the Dixie R. mine. The Mission mill of the Mission Mining & Royalty Co. treated both company and custom ore. Other mine mills operating steadily during the year were the Kansas Exploration (Ritz), Lawyers, Lula Bell (Farmington), and St. Louis No. 4. The Hudson Goodeagle, Roan Bull, Romo, and Smoky Hill mine mills were operated part of the year on a small scale. The M. & W. Mining Co. continued to work the Federal Brewster mine and reopened and operated the adjoining Huttig; the ore was shipped to custom mills. During the year the company obtained a lease on the Ninety-Six Brewster and sank a shaft into new ore bodies, which were brought into production early in 1943. The Beck Mining Co. mill was run steadily in 1942 on company and custom ore from various mines in Oklahoma and Kansas. Tailing mills in Oklahoma that were active in 1941 and continued running in 1942 were the Atlas, Big Chief, Britt & Britt, Cardin Nos. 2 and 3, Semple (Martin), Tri-State Zinc (Ottawa and Sooner), and Western. Tri-State Zinc, Inc., experimented with the H. H. sink-and-float process in the treatment of Tri-State tailings in a commercial-size plant built during the year adjacent to the Sooner mill; the plant was shut down in the latter part of the year. The C. G. & C. Co. leased tailing piles on the Skelton property and acquired the old Skelton mine mill, which was converted into a tailing plant with a capacity of 75 tons an hour; the mill was placed in operation in June and ran the

Digitized by Google

rest of the year except for a temporary shut-down for repairs and improvements.

WISCONSIN

Government premium payments for over-quota production of lead and zinc resulted in a sizable increase in zinc production from old mines and dumps in the Wisconsin and Northern Illinois parts of the Upper Mississippi Valley region in 1942, but the mines in the Iowa part remained idle. The principal producer of finished (smelting-grade) concentrates in the region continued to be the Vinegar Hill Zinc Co., which operated its custom mill near Cuba City on crude ore and zinc-iron-lead rougher jig concentrates purchased from operators throughout the active areas. Plant alterations and installation of additional equipment to increase the capacity of the mill were begun under a Defense Plant Corporation agreement late in 1942 and completed February 22, 1943. The enlarged mill has a capacity of 400 to 500 tons daily, and the equipment includes crushing and sampling units, rougher jigs, two separate ball-mill grinding and selective flotation units, tables, thickeners, and filters. The lead and zinc concentrates produced in 1942 were shipped to smelters outside the State, and the iron concentrates were used to make sulfuric acid in the company plant adjoining the mill. Besides the 79,539 tons of ore and bulk concentrates treated during the year, the company bought for the account of the Metals Reserve Co. about 22,000 tons of crude ore, which was stock-piled pending completion of the mill expansion program. The stock-piled ore is not included in the production for 1942 shown in the tables of this chapter but will be credited to that for the year (probably 1943) in which the ore is reduced to concentrates of smelting grade. This step is necessary before the quantity of metal actually recovered from the ore can be determined.

Shipments to the mill from Northern Illinois in 1942 (comprising the total output from that area) amounted to 22,402 tons of crude ore averaging 11.86 percent zinc and 0.53 percent lead, of which 16,537 tons were reduced to finished concentrates during the year and yielded 1,700 tons of recoverable zinc and 133 tons of lead. Shipments from Wisconsin included both crude ore and rougher jig concentrates. Shippers of jig-mill concentrates comprised the Big Jack Mining Co. (operating the Liberty mine), the C. F. & H. Mining Co. (Mulcahy mine), Coughlin Mining Co., Four S. & B. Mining Co., Little Benny Mining Co. (Monroe mine), and Wm. Blair Baggaley (Kittoe tailing dump). Principal shippers of Wisconsin crude ore, in order of rank, were the Cuba Mining Co., B. A. T. mine; Meloy & Baker, Martin mine; Gill Bros., James and Cleveland mines; R. J. Teske, McCabe mine; Depp Mining Co.; Mathey Mining Co., DeRocher mine; Francis B. Piquette, Trego mine; and Carter & Meloy, Leadmine mine.

The Dodgeville Mining Co. continuously operated its leased group of Dodgeville city lots and 150-ton jig- and flotation-concentration mill. Ore treated totaled 54,774 tons, yielding 2,451 tons of zinc concentrates averaging 61.20 percent zinc and 412 tons of lead concentrates averaging 74.02 percent lead. W. E. Faithorn erected a 600-ton tailing mill equipped with jigs and flotation machines on the Champion property at New Diggings; the mill was operated from July to December and produced 781 tons of 58.5-percent zinc concentrates.

Digitized by Google

At the Field property near Shullsburg the Chestnut Hill Zinc Co. did construction work on a flotation- and table-concentration mill, which was completed and put in operation on tailings in April 1943. During the latter part of 1942 Bureau of Mines engineers examined 45 zinc and lead mines on 14 separate properties in Wisconsin and approved an exploratory drilling project near Hazel Green, on which drilling began early in 1943.

Mine production of lead and zinc in Wisconsin, 1938–42

Year	Lead concentrates		Zinc concentrates (sphalerite)		Metal content [1]			
					Lead		Zinc	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1938	493	$21,050	[2] 3,895	[2] $121,180	320	$29,440	2,073	$199,008
1939	567	29,327	[3] 10,169	[3] 355,915	388	36,472	5,904	614,016
1940	621	34,852	[3] 10,875	[3] 447,396	445	44,500	5,770	727,020
1941	1,639	111,014	[3] 11,685	[3] 594,323	1,225	139,650	6,238	935,700
1942	1,092	104,896	[3] 17,449	[4] 1,028,828	775	103,850	9,426	1,753,236

[1] In calculating metal content of the ores from assays allowance has been made for roasting and smelting losses of both lead and zinc. In comparing the values of ores and metal it should be borne in mind that the value given for the ore is that actually received by the producer, whereas the value of the lead and zinc is calculated from the average price for all grades.

[2] The zinc concentrates shipped in 1938 were a flotation product or raw concentrates roasted at Cuba City, Wis. No raw concentrates were shipped in 1938; about 13,000 tons were produced.

[3] Most of the ore mined in Wisconsin from 1939-42 was first treated in gravity-concentration mills producing bulk concentrates which were re-treated by flotation.

[4] The bulk of the finished zinc concentrates and part of the lead concentrates produced in Wisconsin in 1942 came from a custom mill treating purchased crude ores and low-grade bulk concentrates on which premium payments had been made previously to mine operators; therefore, the value of these concentrates is calculated at market prices. Premium payments not reflected in the value of the finished concentrates amounted to about $399,000 for zinc and $18,500 for lead; part of these payments, however, were for ore which was stock-piled and will not be treated until 1943.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN COLORADO

(MINE REPORT)

By CHAS. W. HENDERSON

SUMMARY OUTLINE

	Page		Page
Summary	317	Metallurgic industry	323
Calculation of value of metal production	318	Review by counties and districts	327
Mine production by counties	320	Golden Cycle mill	332
Mining industry	321	Leadville district	334
Ore classification	322	Cripple Creek district	342

SUMMARY

Colorado mines yielded gold, silver, copper, lead, and zinc valued, in terms of recovered metals, at $19,896,623 in 1942 compared with $23,877,597 in 1941. (See fig. 1.) Gold and silver together represented 58 percent of the total value in 1942 and 77 percent in 1941. Gold production decreased 29 percent in 1942 from 1941. The quantity of silver and copper produced decreased 58 and 84 percent, respectively, lead increased 21 percent, and zinc 105 percent. The number of producing lode mines decreased from 579 in 1941 to 311 in 1942; the number of placer mines decreased from 324 to 68.

The Government, through its agency the Metals Reserve Company, announced that effective February 1, 1942, premiums of 5 cents per pound for copper and 2¾ cents per pound for both lead and zinc would be paid for these metals produced in excess of fixed basic quotas. The ceiling prices for these metals at that date and as of July 1943 were: Copper, electrolytic, 11.775 cents per pound f. o. b. Atlantic seaboard refineries; lead 6.50 cents (New York); and zinc 8.25 cents (St. Louis). The quota for each mine or mining company was based on 1941 production. On December 1, 1942, arrangements for additional premium payments for overquota metal production were announced by the Metals Reserve Company. Operators who could argue their inability to maintain present rate of production without loss of money or who could assure additional output were eligible for these additional Government subsidies for copper, in several steps of 5 cents a pound for each step; for lead and zinc, steps of 2¾ cents a pound.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

Digitized by Google

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1938–42

Year	Gold [1]	Silver [2]	Copper [3]	Lead [4]	Zinc [4]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1938	$35.00	[5] $0.046+	$0.098	$0.046	$0.048
1939	35.00	[6] .678+	.104	.047	.052
1940	35.00	[7] .711+	.113	.050	.063
1941	35.00	[7] .711+	.118	.057	.075
1942	35.00	[7] .711+	.121	.067	.093

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.
[2] Treasury buying price for newly mined silver.
[3] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Company for over-quota production but excludes value of foreign copper delivered to Metals Reserve Company for domestic consumption.
[4] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Company for over-quota production.
[5] $0.64646464. [6] $0.67878787. [7] $0.71111111.

Annual figures for the 5 years ended with 1942 and total production from 1858 are given in the table that follows. To the end of 1941 Colorado had produced more silver than any other State, but the decreased output in 1942 allowed Montana to pass it.

Mine production of gold, silver, copper, lead, and zinc in Colorado, 1938–42, and total, 1858–1942, in terms of recovered metals

Gold.—The output of recoverable gold from lode mines in Colorado decreased from 349,652 fine ounces in 1941 to 246,010 fine ounces in 1942; the production of gold from placer mines decreased 7,760 fine ounces.

Silver.—Mine production of recoverable silver in Colorado was 3,096,211 fine ounces in 1942, compared with 7,301,697 fine ounces in 1941. Dry and siliceous ores yielded 69 percent of the total silver; zinc and zinc-lead ores, 29 percent; and other types of ores, with a very small quantity of silver from placer mines, 2 percent.

Copper.—The output of recoverable copper from mines in Colorado in 1942 was 2,204,000 pounds compared with 13,496,000 pounds in

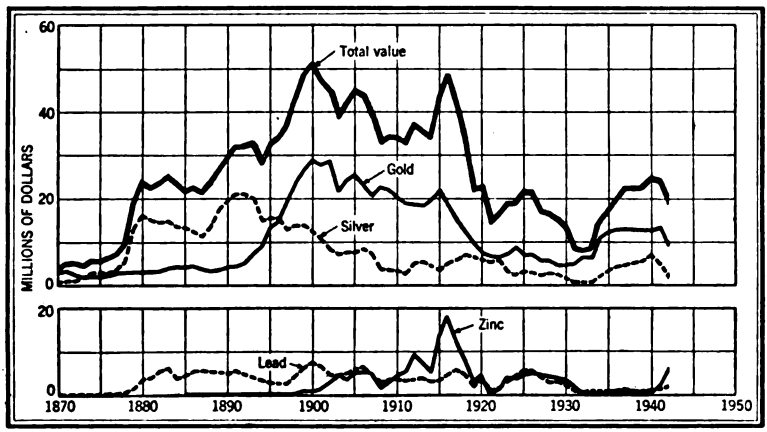

FIGURE 1.—Value of mine production of gold, silver, copper, lead, and zinc in Colorado, 1870–1942. The value of copper has been less than $2,000,000 annually, except in a few years.

1941. Eagle County produced 29 percent of the State total in 1942 compared with 83 percent in 1941.

Lead.—The mine production of recoverable lead in Colorado was 30,362,000 pounds in 1942 compared with 25,148,000 pounds in 1941. Zinc-lead ore yielded 67 percent of the total lead; dry and siliceous ores 28 percent; and lead, copper, zinc, and lead-copper ores together, 5 percent.

Zinc.—The output of recoverable zinc from mines in Colorado increased 105 percent in quantity in 1942 over 1941. Largely responsible for this increase was the New Jersey Zinc Co. Empire Zinc Division Eagle mine at Gilman, Eagle County, which resumed mining and milling zinc-lead ore in June 1941 and continued throughout 1942. Other principal zinc-producing districts in 1942 were: California (Leadville), Lake County; Pioneer (Rico), Dolores County; Ten Mile, Summit County; and Buckskin, Park County.

[1] Dragline and power-shovel excavators with sluices or special amalgamators.

MINING INDUSTRY

The variation and complexity of Colorado ores allowed mines to meet the shifting and complexing Government orders, as well as changes in the prices for metal. Except for the Cripple Creek district, virtually all the ores in Colorado districts—although chiefly valuable for gold and silver—contain some zinc, often discarded. A change in selection of ore and in metallurgy converted many mines

Digitized by Google

into producers of zinc concentrates or products containing recoverable zinc. This change is shown clearly by a comparison of the county and district tables for 1939 and 1942.

Effective March 2, 1942, the War Production Board issued an amendment to Order P–56, placing the mining industry on a par with manufacturers of war materials. Among other instructions, this amendment provided that mines at which the value of gold, silver, or both produced exceeded 30 percent of the value of the total metal output would no longer be entitled to priority ratings assigned under Order P–56. This amendment deprived virtually all gold mines in Colorado of essential equipment and supplies and forced many operators to close long before the Gold Mining Limitation Order of October 8, 1942. Later, upon appeal, this amendment to Order P–56 was voided.

Dredging operations ceased immediately upon the date set for closing by Order L–208—called the Gold Mining Limitation Order (see Gold and Silver chapter for text of order). Cripple Creek lode district, upon appeal, was given a reprieve until June 8, 1943, but the exodus of miners that had begun in March greatly increased. Split-check lessees, indigenous to that district (and the producers of 80 percent of the ore), who had generally kept at work, began drifting away after the issuance of Order L–208 and continued to do so in 1943, with the result that several of the largest mines ceased operations in March.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Colorado in 1942, with content in terms of recovered metals

Source	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Dry and siliceous gold ore	932,145	188,682	293,231	597,574	2,138,734	735,874
Dry and siliceous gold-silver ore	192,709	25,077	399,586	122,738	4,012,497	780,000
Dry and siliceous silver ore	88,132	2,407	1,428,333	716,619	2,477,385	284,000
	1,212,986	216,166	2,121,150	1,436,931	8,628,616	1,799,874
Copper ore	208	44	3,189	26,286	865	----------
Lead ore	6,418	1,451	61,717	26,513	1,442,554	----------
Lead-copper ore	22	24	493	2,192	3,483	----------
Zinc ore	590	6	2,514	2,200	40,822	429,899
Zinc-lead ore	577,162	28,319	902,946	709,878	20,245,660	62,200,227
	584,400	29,844	970,859	767,069	21,733,384	62,630,126
Total, lode mines	1,797,386	246,010	3,092,009	2,204,000	30,362,000	64,430,000
Total, placers	----------	22,617	4,202	----------	----------	----------
	1,797,386	268,627	3,096,211	2,204,000	30,362,000	64,430,000
Total, 1941	2,222,786	380,029	7,301,697	13,496,000	25,148,000	31,444,000

METALLURGIC INDUSTRY

The total ore sold or treated in Colorado was 1,797,386 tons in 1942 compared with 2,222,786 tons in 1941. The quantity of zinc-lead ores sold or treated increased from 434,200 tons in 1941 to 577,162 tons in 1942, most of the increase coming from Eagle County; dry and siliceous ores decreased from 1,572,763 tons to 1,212,986; copper ore decreased from 207,678 tons to 208, owing almost entirely to conversion to zinc-lead mining and milling at the New Jersey Zinc Co. Empire Zinc Division Eagle mine at Gilman, Eagle County; lead ore decreased from 7,917 tons to 6,418; and zinc ore increased from 224 tons to 590.

Direct smelting ore comprised 3 percent of the State total output of ore in 1942 as compared with 11 percent in 1941. The Arkansas Valley lead bullion-leady copper matte smelter at Leadville purchased most of the gold, silver, and gold-silver-lead-copper ores and concentrates shipped to smelters during the year.

Ore and concentrates were shipped to smelters in other States as follows: Zinc-lead sulfide ores and concentrates from Lake and Saguache Counties to Coffeyville, Kans.; zinc concentrates from Clear Creek, Dolores, Ouray, Park, Pitkin, San Juan, San Miguel, and Summit Counties to Amarillo, Tex.; and silver-gold-copper-lead ore from Eagle County, gold-silver-copper ores and concentrates from Gilpin, Mesa, Montrose, Ouray, Rio Grande, and San Juan Counties, and zinc-lead-copper-silver-gold ores and concentrates from Garfield, Lake, Ouray, Saguache, and San Juan Counties to Utah smelters.

The quantity of gravel handled in 1942 by two floating connected-bucket dredges, one dragline floating dredge, and one dry-land dredge was approximately 2,919,406 cubic yards. Specific data on yardage handled at small-scale placer operations are not obtainable because the operators do not know the quantity of gravel sluiced.

Mine production of metals in Colorado in 1942, by methods of recovery, in terms of recovered metals

	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore and concentrates amalgamated [1]	717,716	60,233	15,906	----	----	----
Ore, old tailings, concentrates, sands, and slimes cyanided [2]	[3] 272,889	86,132	13,202	----	----	----
Concentrates smelted	140,590	91,219	2,446,104	1,467,753	27,800,925	63,874,212
Ore smelted	48,173	8,426	616,797	736,247	2,561,075	555,788
Placer [1]	----	22,617	4,202	----	----	----
	----	268,627	3,096,211	2,204,000	30,362,000	64,430,000
Total, 1941	----	380,029	7,301,697	13,496,000	25,148,000	31,444,000

[1] Quicksilver used by amalgamation mills was 3,429 pounds. Placer mines used approximately 115 pounds.
[2] Cyanide (in terms of 96- to 98-percent NaCN) used was 529,747 pounds.
[3] Comprises 253,551 tons of sands and slimes from ore and iron concentrates first roasted and amalgamated and 19,338 tons of combined flotation concentrates and crude ore cyanided direct.

ADAMS COUNTY

Sand and gravel handled in the washing plant of the Brannan Sand & Gravel Co. on Clear Creek, north of Denver, yielded gold as a byproduct.

BOULDER COUNTY

Central (Jamestown) district.—The Wano mine was again, as in 1941, the largest producer of gold in the Central district; it was operated by the owners, who shipped crude ore to the Golden Cycle mill at Colorado Springs. Mining of gold ores ceased in May for the duration of the war, but the operator began experiments in milling fluorspar from the property and from the Emmett mine. A lessee at the Smuggler group shipped gold ore to the Golden Cycle mill until operations were suspended November 12 by the Gold Mining Limitation Order. The General Chemical Co. entered the district in 1942 to mine fluorspar and incidentally shipped gold ore to the Golden Cycle mill during the latter part of the year from surface dumps on the Invincible claim. Other producers of gold in the Central district were the Black Rose group, the Emmett, and the John Jay mine. In milling fluorspar ore, 24 tons of lead-silver concentrates were made and shipped from the Emmett mine to the smelter at Leadville.

Gold Hill district.—Slide Mines, Inc., was the leading producer of gold, silver, copper, and lead in the Gold Hill district. The company operated its Slide-Klondyke-Twin group of mines and 70-ton gravity- and flotation-concentration mill continuously until August, when a change-over of most of the crew and equipment was made to operate the company tungsten mines in the Sugar Loaf district. Gold concentrates caught on burlap tables between the classifier and Wilfley tables were amalgamated, and the remainder—containing gold, silver, copper, and lead—were shipped to the Leadville smelter. Most of the ore from the other producing mines and dumps in the district was shipped to the Golden Cycle mill. Other sizable producers, in order of gold output, were the Ingram group, Gardner, Nil Desperandum, Sunshine, and the Emancipation group. Zinc-lead ore containing 7,803 pounds of zinc, 8,319 pounds of lead, 281 ounces of silver, and 14.80 ounces of gold were shipped from the Home Sweet Home to the Midvale (Utah) custom concentrator, in addition to the shipment of 1,206 tons of gold ore to the Golden Cycle mill.

Grand Island district (Nederland).—The Donora Mining Co. operated the Boulder County mine and 70-ton jig- and flotation-concentration mill at Cardinal under lease until June. About 100 tons of gold-silver-lead concentrates were produced and shipped to the Leadville smelter. The other producing mines in the district were the Enterprise group, the Blue Bird, and the Golden Reward.

Magnolia district.—The producing mines in the Magnolia district in 1942, in order of gold output, were the Cash-Rebecca, Keystone, India, and Hereafter. All ore was shipped to the Golden Cycle mill.

Sugar Loaf district.—Most of the ore produced from mines and dumps in the Sugar Loaf district in 1942 was shipped to the Golden Cycle mill. The Poorman group, worked continuously by lessees until October, was again the largest producer of gold in the district; it was followed by the Livingston, Alpine Horn, Nancy, Empress, and Herold. The silver output of the district came chiefly from the Nancy.

556250—43——22

Digitized by Google

Ward district.—The Boston and Utica mines were operated throughout 1942 by the Ward United Mines Co. and were the leading producers of copper in the Ward district and in Boulder County. Low-grade ore concentrated at the company 25-ton concentration-flotation mill and crude smelting ore shipped to the smelter at Leadville contained (in smelting ore and concentrates combined) 1,586 ounces of gold, 1,450 ounces of silver, and 29,112 pounds of copper. Small tonnages of concentrates were also shipped to the Leadville smelter from the Columbia and Black Jack mines at Ward.

CHAFFEE COUNTY

Chalk Creek district.—Lessees continued to operate the Mary Murphy mine in 1942 and shipped 40 tons of gold-silver-lead-copper-zinc ore to the Midvale (Utah) custom milling plant and 10 tons to the Leadville smelter. The ore contained 41.68 ounces of gold, 447 ounces of silver, 897 pounds of copper, 8,043 pounds of lead, and 16,293 pounds of zinc.

Granite district.—Ernest Dial operated the Marion Bell lode from June until September and shipped 1 ton of gold-silver ore to the Leadville smelter and retort and amalgam grains to the Denver Mint. The Marion Bell was the only lode operation in the Granite district in 1942. Len Savage operated his Gold Basin placer until September, using a power shovel and screening-sluicing plant. Intermittent operations on the Channel, Lost Canyon, and Independent placers produced small lots of gold, which were shipped to the Denver Mint.

Monarch district.—Production from the Monarch district comprised 82 tons of gold-silver-lead-copper ore, which was shipped by a lessee from the Madonna group to the Leadville smelter.

CLEAR CREEK COUNTY

Alice district (Yankee, Lincoln).—New Lombard Mines, Inc., operated the Lombard mine until August 1942 and milled the ore in the Lombard mill; the product was gold bullion shipped to the Denver Mint and 148 tons of lead-silver-gold concentrates shipped to the Leadville smelter. The Gold King mine yielded 29 tons of gold ore, which were shipped to the Golden Cycle mill at Colorado Springs.

Argentine district.—The only output from the Argentine district in 1942 was from Buckley Bros. operations on the Hamill tunnel group; 506 tons of silver ore containing some silver and lead were produced, of which 375 tons were concentrated in a local custom mill and 131 tons shipped crude to the Leadville smelter.

Empire district.—In 1942 Minnesota Mines, Inc., operated continuously its Crown Prince group of mines and 250-ton (daily) flotation-cyanidation mill and was again the largest producer of gold in the county, producing over one-third of the county total. (See Minerals Yearbook, 1941, for method of ore treatment.) Copper Cone, Inc., produced 559 tons of gold-silver-copper ore from the Upper Union-Gold Fissure group; the ore was treated in the Clear Creek-Gilpin Co. mill at Idaho Springs, and the concentrates were shipped to the Leadville smelter. Other small producers included the Empire tunnel, Gold Dirt, and Omaha properties.

Griffith district.—The Smuggler mine, largest producer of lead and zinc in the county, was worked throughout the year by the Mile High Mining Co. Zinc and lead concentrates were produced in the Silver

Digitized by Google

Leaf mill at Silver Plume and shipped to the Amarillo (Tex.) and Leadville smelters. Fargo Mines, operators at the Fargo mines, and Wallace K. Howard at the Mendota group of mines made several small shipments of ore to the Midvale (Utah) custom concentrator. The Burleigh tunnel was rehabilitated to the Phillips vein, and sampling was also done in the district by the Federal Bureau of Mines during the latter half of the year. Several shipments of dump ore were made from the Dives-Pelican group in 1942 to the Proctor Milliken mill, east of Idaho Springs, by the Silver Plume Mines, Inc.

Idaho Springs district.—The Alma-Lincoln Mining Co. continued to operate its Lincoln-South Lincoln-Elliott Barber group and 150-ton flotation mill throughout 1942 and treated 16,624 tons of ore (mill was operated 6 days a week, one shift a day), compared with 25,019 tons in 1941. The company also leased and operated the Cardigan group until April 16, 1942, and treated the ore at the Alma-Lincoln mill. Inter-Mountain Mines, Inc., operated the Dona Juanita-Maude Monroe group of mines from January 1 until May 1 and mined about 6,000 tons of ore, which were milled at the Silver Spruce mill. The Williams Mining Co. operated the Williams mine in 1942 and treated the ore at its Missouri Lake mill in Gilpin County. Until October LeRoy Giles & Co. continued to ship gold-silver ore from the Dixie No. 4 to the Ruth custom mill. Other sizable producers of gold-silver-lead-copper ores were the Shafter, Freighter's Friend, Idaho Bride, and Specie Payment group. Custom mills operating intermittently in the Idaho Springs district included the Clear Creek-Gilpin Co., Ruth, Chicago Creek, Proctor Milliken, and Silver Spruce.

Montana district.—Virtually all production of ore from the Montana district in 1942 comprised 3,511 tons of lead-silver-gold ore from the Joe Reynolds and 2,595 tons from the Red Elephant group. Other small producers in 1942 were the Columbine and the Golden Calf.

Trail Creek district.—Lamartine Mines, Inc., operated the Lamartine-Falcon group of mines throughout the year and was the second-largest producer of gold in Clear Creek County. About 26,060 tons of ore were treated in the company mill by flotation, supplemented by jigs in the ball mill-classifier circuit to extract free gold for amalgamation. Bullion sold to the Denver Mint contained 1,436 fine ounces of gold and 372 fine ounces of silver; and concentrates shipped to the Leadville smelter contained 1,908 ounces of gold, 3,682 ounces of silver, 140,347 pounds of lead, 65,606 pounds of zinc, and some copper. Other sizable producers in the Trail Creek district were the Wheatland, Lone Tree, and Phoenix mines.

CUSTER COUNTY

Hardscrabble district.—The output from the Hardscrabble district in 1942 comprised 16 tons of lead ore from the Passiflora mine and 1 ton each from the Four Aces and High Kicker-Wild Girl group.

DOLORES COUNTY

Pioneer district (Rico).—The Rico Argentine Mining Co. operated its group of mines and 135-ton selective-flotation mill continuously in 1942 and milled 34,735 tons of zinc-lead-silver-gold-copper ore,

Digitized by Google

compared with 35,666 tons in 1941. The products of the mill were lead-silver concentrates (carrying some copper, zinc, and a little gold) shipped to the Leadville smelter and zinc concentrates (carrying also silver, lead, copper, and a little gold) shipped to the Amarillo (Tex.) smelter. The zinc concentrates averaged 48.9 percent zinc, and the lead concentrates averaged 67.8 percent lead. Markey Bros. operated the Yellow Jacket group under lease and shipped crude zinc-lead ore (carrying some silver, copper, and a little gold) to custom mills in Utah.

EAGLE COUNTY

Red Cliff district (Battle Mountain).—In 1942 the Red Cliff district ranked first among Colorado districts in output of copper and zinc. The New Jersey Zinc Co. Empire Zinc Division Eagle mine and mill at Gilman were operated continuously in 1942; its 600-ton zinc-lead mill was operated only from June through December in 1941. The company mined and shipped very much less copper-iron-silver-gold sulfide smelting ore in 1942 than in 1941. A lessee on the Cora claim at Belden shipped 55 tons of gold-silver smelting ore in 1942.

EL PASO COUNTY

GOLDEN CYCLE MILL

The Golden Cycle custom mill at Colorado Springs recovered 48 percent of the total Colorado output of gold from lode mines in 1942. It treated 378,434 tons of ore averaging 0.308 ounce of gold to the ton compared with 532,127 tons of ore averaging 0.3038 ounce in 1941. Of the total ore treated in 1942, 362,460 tons were gold-[silver]-sulfotelluride ores from the Cripple Creek district (Teller County), and 15,974 tons comprised miscellaneous gold and gold-silver ores from other districts, mainly in Boulder, Clear Creek, and Gilpin Counties. As ores purchased vary in character and grade, the metallurgy is not always the same. Essential features of ore treatment are described in this section, Minerals Yearbook, 1941.

Milling at Colorado Springs was curtailed in October by the provisions of the Gold Mining Limitation Order. A reprieve was granted to December 8, 1942, and another reprieve on that date (in response to an appeal filed with the War Production Board) permitted the mill to operate for 6 months, or until June 8, 1943, during which time equipment should be added to treat zinc-lead ores. Under the terms of this reprieve the mill was allowed to continue to treat Cripple Creek ores, with a provision also to be allowed to continue to treat siliceous gold-bearing ores to serve as a lighter-weight product to mix with iron concentrates (containing gold and silver) from the zinc-lead-iron ores. Conversion and enlargement of the flotation-mill unit within the amalgamation-cyanidation plant were begun in late December 1942 and completed in February 1943. The capacity of the flotation mill (changed from bulk concentration to selective) was increased from 300 to 500 tons per day. Between February and May 1943, 4,000 tons of zinc-lead ore from Saguache, Lake, Fremont, and Clear Creek Counties were treated in the flotation unit of the plant. A further reprieve was granted June 8, 1943, permitting operations until August 8. Zinc-lead bulk concentrates from the 1,000-ton Ore & Chemical Co. "sink-and-float" mill at Leadville

Digitized by Google

(to be completed in July or August 1943) will be shipped to the Golden Cycle mill for selective concentration.

FREMONT COUNTY

The Monarch Galena Co. operated the Cotopaxi mine in the Cotopaxi district the last 6 months of 1942 and shipped 34 tons of zinc-copper-silver ore to the United States Smelting, Refining & Mining Co. custom concentrator at Midvale, Utah.

GILPIN COUNTY

Southern districts (*Blackhawk, Central City, Nevadaville, Russell Gulch*).—Twenty-one lode and 13 placer mines were productive in the Southern districts in 1942, as compared with 43 lode and 76 placer mines in 1941. The output of gold, silver, and copper decreased sharply in 1942, but an increase was noted in the production of lead. The Pittsburg-Notaway group of mines and 100-ton flotation mill were operated continuously under lease in 1942 by Kingmill Mines, Inc. This group yielded nearly two-thirds of the total output of gold from lode mines in the Southern districts and was the largest producer of silver and copper in Gilpin County in 1942. The gold-silver-copper concentrates were shipped to the Leadville smelter. The Queen Mineral Ranch, operated by Cole Godsey and associates, produced over half of the year's output of lead from Gilpin County. The California-Hidden Treasure Mines Co. worked the Monmouth-Kansas mine throughout the year through the Argo tunnel, sending the ore produced to the Clear Creek-Gilpin mill at Idaho Springs (Clear Creek County) for treatment. The recovery in bullion shipped to the Denver Mint and the content of concentrates sold to the Leadville smelter totaled 703 ounces of gold, 3,103 ounces of silver, 12,772 pounds of copper, and 8,883 pounds of lead. Lessees operated the New Brunswick mine and 15-ton stamp amalgamation-table concentration mill until February, when work stopped because of the high cost of labor and materials. Ore was also shipped to custom mills in Clear Creek County from the Anchor, Justice, West Notaway, Pyrenees, Rocky Mountain, and other mines and dumps in the Southern districts.

Small-scale placers working with power shovels or draglines and screening and sluicing plants in 1942 included the MacElwee, Peerless, Morgan, and Russell Gulch placers.

Northern districts.—The Perigo group was worked on a small scale by lessees during part of 1942. Most of the ore was concentrated in the Monarch 75-ton flotation mill on the property, and the gold-silver concentrates were shipped to the Leadville smelter. Other producing mines in the district were the Champion and Evergreen.

GRAND COUNTY

Small lots of silver-lead ore were shipped to the Leadville smelter in 1942 from the Bobtail claim in La Plata district and the Ready Cash mine near Jones Pass.

Digitized by Google

GUNNISON COUNTY

Gold Brick district.—The Carter Mines Co. continued to operate its mine and mill on Gold Creek until October 15, 1942, when production ceased in compliance with the Gold Mining Limitation Order. The ore was treated by amalgamation and by flotation and gravity concentration. Burleson Mines, Inc., operated the Raymond group and 75-ton flotation mill from January 1 to June 25, 1942; the mill recovered 46 tons of bulk lead-gold-silver concentrates, which were sold to the Leadville smelter. Crude smelting ore was shipped from the Chicago and Gold Links properties.

Taylor Park district.—In 1942 the Star and Thunderbird mines shipped 88 and 45 tons, respectively, of ore containing zinc, lead, copper, silver, and gold to the Midvale (Utah) custom mill.

Tomichi district.—The Callahan Zinc-Lead Co., Inc., operated the Akron mine throughout 1942; operations before September were confined to development only. Zinc-lead-silver ore (286 tons) was shipped to the Midvale (Utah) custom mill.

HINSDALE COUNTY

Galena district.—Davis Gold Mines shipped 11 tons of lead-silver-gold concentrates, milled in 1941 from Eldorado mine ore, to the Leadville smelter in 1942. The Base Metal Corporation operated under lease the Ute and Ulay group and flotation mill and produced 263 tons of lead-silver-gold concentrates

JEFFERSON COUNTY

Placer gold and silver were the only metals produced in Jefferson County in 1942. The greatest part of the placer gold produced during the year was recovered by W. B. Kerkling from the Bertrand gravel pit and the Tresize placer. The American Smelting & Refining Co. explored the Malachite mine, near Starbuck, by diamond drilling but did not exercise its option.

LAKE COUNTY

LEADVILLE DISTRICT

The American Smelting & Refining Co. operated its Arkansas Valley lead bullion-leady copper matte smelter continuously (one furnace) in 1942 on ores and concentrates purchased from operators in virtually every active mining district in Colorado. Receipts of ore and concentrates totaled 94,659 tons compared with 121,297 tons in 1941.

The largest mining enterprise in the Leadville district in 1942 was that of the Resurrection Mining Co., which operated the Resurrection mine and 300-ton selective-flotation mill throughout 1942. In 1941 the company purchased the Yak tunnel and the mining claims of the Yak Mining, Milling & Tunnel Co. Construction was begun on a modern 250- to 300-ton flotation mill at the portal of the Yak tunnel in California Gulch; this mill was completed and production of concentrates from mine ore hauled through the Yak tunnel was started in January 1942. Total ore treated in the mill in 1942 amounted to 91,642 tons, of which 17,165 tons were dump ore from the Resurrec-

Digitized by Google

tion dump, milled for the American Smelting & Refining Co. Zinc-lead-gold-silver concentrates produced totaled 12,009 tons, containing 10,100 ounces of gold, 116,775 ounces of silver, 5,181,323 pounds of lead, and 7,011,312 pounds of zinc. Lead concentrates were shipped to the Leadville smelter; zinc concentrates were shipped to Amarillo, Tex. Development in 1942 consisted of 30 feet of shaft, 8,664 feet of drift, 1,181 feet of raises, and 2,753 feet of diamond drilling. To attract workers to this operation the management purchased and remodeled two large buildings in Leadville to make apartments for mine personnel. Work was commenced on a second milling unit designed to double the capacity of the 1942 milling operation; the new unit is expected to be completed and in operation in July 1943.

The California Gulch Mining & Milling Co. operated its two gravity- and flotation-concentration and amalgamation mills—one 75- to 125-ton capacity and one 450-ton capacity—during most of the year on ores from the Wolftone dump, Ibex dump, Valley lease, and Fortune lode. The Gold Mining Limitation Order of October 1942 forced the company to convert its small mill to the recovery of zinc and lead to remain in operation. Conversion of the larger mill to selective flotation was in progress in the early part of 1943. The John Hamm Mining & Milling, Ltd., operated its 300-ton amalgamation-gravity concentration-flotation mill the entire year on ore from the Ibex and Maid of Erin dumps. Addition of a jig plant to handle dump ores carrying zinc and lead was in progress at the close of the year. Andy Caine & Co. treated ore from the Fanny Rawlings mine by table concentration and amalgamation in the leased Norton mill. Gold-silver bullion recovered was sold to the Denver Mint; 90 tons of concentrates containing 36 ounces of gold, 537 ounces of silver, 8,632 pounds of lead, and a little copper were shipped to the Leadville smelter. The principal shippers of smelter ore to the Leadville smelter and smelters in Utah (in approximate order of tonnage) were the Breece dump, Galligher dump, Ibex, Rock Hill, New Monarch-Treasure Vault, Dolly B, Tucson, Little Jonny, Galligher lease, Fortune, Little Ellen, Golden Eagle, St. Louis tunnel, Breece, and "Lillian."

The Ore & Chemical Co. early in 1942 sampled dumps and determined 365,000 tons of mill-grade dump ore averaging 5 percent zinc and 3 percent lead; in November 1942 it began construction of a 1,000-ton "sink-and-float" mill southwest of Leadville near the Arkansas Valley smelter. The mill is scheduled for completion in July or August 1943; production of 125 tons of bulk zinc-lead concentrates (containing 15 percent zinc and 8 percent lead) a day is anticipated. The concentrates produced will be shipped to the Golden Cycle mill for selective flotation. Wartime demands for increased production of zinc and lead prompted the Federal Bureau of Mines to initiate two projects in the Leadville area designed to make available more ore for the production of these metals. The sampling of several old mine dumps in the fall and winter of 1942 proved 370,000 tons of dump ore. If funds are made available, the Bureau of Mines will drive a 2.55-mile tunnel to unwater the mines of Carbonate Hill, Evans Gulch, and Fryer Hill areas north and east of Leadville and the Downtown area within the city. Bureau of Mines engineers began planning and design studies of this project in September 1942. It is anticipated that this tunnel will drain 65 to 90 percent of the mine water of the Leadville area above the 9,950-foot or

Digitized by Google

9,970-foot altitude, whichever level of the portal is chosen. An appropriation of $1,500,000 has been approved by the Bureau of the Budget to cover costs of driving.

OTHER DISTRICTS

Slightly less than 400 tons of ore (mostly dry and siliceous gold, gold-silver, and silver and one small lot of lead-silver) were shipped in 1942 from mines in Lake County outside the Leadville district. Producing lode properties comprised the Amity, Dinero, and Dinero dump in the St. Kevin-Sugar Loaf district; and the Gordon-Bengal Tiger in the Twin Lakes district. Sluicing on the Derry Ranch placer in the Box Creek district recovered some gold.

LA PLATA COUNTY

California (or La Plata) district (Hesperus, La Plata).—Very small quantities of gold-silver ore were shipped by truck to the Leadville smelter in 1942 from the Bessie G and Nonpareil lodes. A lessee on the Mountain Lilly group shipped 19 tons of gold-silver ore to the Midvale (Utah) custom mill.

MINERAL COUNTY

Creede district.—The Emperius Mining Co., which in 1942 controlled nearly all mining properties in the Creede district, operated a group of mines and its 100-ton flotation mill at near capacity throughout 1942. Owing to a shortage of manpower, an average of 120 men was employed at the operation as compared with 160 in 1941. Lead-silver-gold concentrates produced were shipped to the Leadville smelter. Mines shipping to the mill comprised the Amethyst group, Commodore, New York-Last Chance-Pittsburg, Equinox, Ochre, and Happy Thought. From all the above producing properties except the Happy Thought, high-grade lead-silver-gold ore was shipped direct to the Leadville smelter.

MONTEZUMA COUNTY

The Red Arrow Gold Corporation operated its Red Arrow mine and 25-ton amalgamation-concentration mill from January to November 17, 1942. Gold-silver bullion recovered was sold to the Denver Mint. Gold-silver-copper concentrates produced by jigging and blanket-tabling were shipped to the Leadville smelter. The Outwest Mining Co. shipped 19 tons of gold-silver ore from the Outwest property adjoining the Red Arrow.

MONTROSE COUNTY

La Sal district.—Lessees at the Cashin group shipped 138 tons of copper-silver ore to the Tooele (Utah) copper plant.

OURAY COUNTY

Red Mountain district.—Several carloads of zinc-lead-silver ore were shipped in 1942 to the Midvale (Utah) custom mill from the Beaver, Micky Breen, Barstow dump, Rico, and Ida L in the Red Mountain district. Wm. McCullough and G. A. Franz leased the Mountain

Digitized by Google

King dump in August and began trucking ore on September 1 to the Franz mill for treatment; 1,200 tons were milled, yielding 158 tons of concentrates, which were shipped to the Midvale (Utah) custom mill for further concentration.

Sneffels district.—King Lease, Inc., operated the Camp Bird mine and the King Lease 100- to 125-ton amalgamation-flotation mill continuously in 1942. (See Minerals Yearbook, 1941, for methods of ore treatment.) A lessee on the Trust-Ruby claim shipped 5 tons of lead-silver-gold concentrates recovered from 191 tons of ore milled in the Franz custom mill. Zinc-lead-silver ore totaling 36 tons was shipped to the Midvale (Utah) custom mill from the Atlas and Mountain Top claims.

Uncompahgre district.—G. A. Franz, Inc., operated its 120-ton flotation mill 2 miles north of Ouray in 1942 on custom ores from the Mountain King dump in the Red Mountain district; Trust-Ruby in the Sneffels district; and the Bachelor, Senorita, Mineral Farm, and Wedge in the Uncompahgre district. During the year, 4,187 tons of ore were milled, averaging 0.02 ounce of gold and 6.5 ounces of silver to the ton, 0.6 percent copper, 4.1 percent lead, and 4.6 percent zinc. Lead-silver concentrates were shipped to the Leadville smelter and zinc concentrates to the Amarillo (Tex.) smelter and the Midvale (Utah) concentrator. The McCullough Lease shipped 840 tons of gold-silver-copper ore to the Midvale (Utah) smelter from the Wanakah group, in addition to shipping 28 tons of gold-silver ore to the Leadville smelter from the Wanakah and American Nettie groups. The J. R. Sonza lease on the Bachelor Consolidated group of claims completed hauling the remainder of the Wedge dump to the Franz mill in 1942. Lead concentrates produced, amounting to 140 tons, were shipped to the Leadville smelter. Small tonnages of smelting ore were also shipped from the Newsboy, Senorita, and U. S. mines.

PARK COUNTY

Alma Placers district.—Jack Richards was the principal producer on the Alma Placers in 1942 but ceased operations in September 1942. A lessee on the Gumaer placer operated from May 18 to June 22, 1942. At both operations the gravel was excavated from open pits by power shovels and trucked to central sluicing plants for treatment. The gold recovered was sold to the Denver Mint.

Beaver Creek district.—The Timberline Dredging Co. operated its electric floating connected-bucket dredge (dredge No. 1) on Beaver Creek 2 miles north of Fairplay from April 9 to October 15, 1942, when operations were stopped in deference to War Production Board Order L–208. The dredge, equipped with 84 7½-cubic foot buckets, handled 520,065 cubic yards of gravel in 1942, yielding 1,907 fine ounces of gold and 415 fine ounces of silver. Sluicing at other placers on Beaver Creek by Ray Wood and H. D. Myers recovered some gold, which was sold to the Denver Mint.

Buckskin district.—The Buckskin Joe Mines, Ltd., operated the Phillips group of mines in Buckskin Gulch and the Alma-Betts 50-ton selective-flotation mill in Mosquito Gulch throughout 1942. The mill treated 5,652 tons of ore, yielding 1,560 tons of concentrates containing 1,469 ounces of gold, 9,965 ounces of silver, 33,467 pounds of copper, 133,043 pounds of lead, and 988,205 pounds of zinc. Lead concentrates carrying some gold, silver, copper, and zinc were shipped

Digitized by Google

to the Leadville smelter; zinc concentrates carrying some gold, silver, copper, and lead were shipped to the Amarillo (Tex.) smelter. A lessee on the Gold Ridge mine shipped 66 tons of zinc-lead ore to the Midvale (Utah) custom mill and 23 tons of gold-silver-lead ore to the Leadville smelter. Sluicing in Buckskin Gulch recovered a small amount of gold.

Consolidated Montgomery district.—The Magnolia Gold Mining Co. worked the Lee Goss lode under lease throughout 1942 and produced 880 tons of gold-silver ore, containing a little copper, which was trucked to the Leadville smelter. The company 50-ton mill in Montgomery Gulch was not operated during the year. A small lot of lead-silver ore was shipped to the Leadville smelter from the Webber group.

Fairplay district.—The South Platte Dredging Co. continued to operate (until closed by Government order October 15, 1942) its steel floating connected-bucket dredge on bench ground along the Platte River 1½ miles southeast of Fairplay. The dredge is powered by electricity and is equipped with 108 12-cubic foot buckets. The Snowstorm placer 2 miles north of Fairplay yielded a substantial output during the year. Five operators, one of which (the Timberline Dredging Co.) used a dragline (8-cubic yard bucket) and floating Bodinson washing plant (called dredge No. 2), worked the gravels on the property. Small, intermittent sluicing operations were conducted at other placers on the Platte River near Fairplay.

Mosquito Creek district.—The London Mines & Milling Co. maintained production throughout 1942 from its consolidated group of mines on London Mountain and continued to be the principal metal producer in the Mosquito Creek district and in Park County. Dump and mine ore totaled 71,258 tons and was treated in the company 200-ton flotation- and gravity-concentration mill 7 miles west of Alma on South Mosquito Creek. Besides gold—the chief metal of value—the concentrates produced contained some silver, a little copper, and considerable lead and zinc and were sold to the Leadville smelter. James Redman operated his 150-ton Record mill from July 30 to August 5, 1942, and again for a few days in December on ore from the American mine. The London Butte Gold Mines Co. operated its Butte mine and 100-ton flotation mill 7 miles northwest of Alma throughout 1942 and treated 14,138 tons of ore, which made 618 tons of concentrates containing 2,720 ounces of gold, 1,685 ounces of silver, 95,004 pounds of lead, and a small amount of copper. The concentrates produced were shipped to the Leadville smelter. Several shipments of lead ore from the American, Ophir, and Hock Hocking claims were made to the Leadville smelter, and dump ore from the Orphan Boy mine was milled in the district. Reconstruction Finance Corporation granted Class A and Class B loans in 1942–3 totaling $80,000 to mines in the Mosquito Creek, Buckskin, and Consolidated Montgomery districts, all contingent on production of zinc-lead-[silver-gold] ore.

Tarryall district.—Cooley Bros. continued to operate the Peabody-Volz group of placers 2 miles north of Como under lease from April 4 to October 15, 1942, when operations were closed by the Gold Mining Limitation Order. The 3,000-cubic yard (per day) dragline floating dredge recovered 3,858 ounces of gold and 424 ounces of silver in 1942. The Sterling Mining Co. operated its 1½-cubic yard dragline and four-

Digitized by Google

bowl land dredge on the Little Mint-Storming Jordan placer on Tarryall Creek 7 miles below Como from May 20 to September 14, 1942.

PITKIN COUNTY

Roaring Fork district (*Aspen*).—The Midnight Mining Co. operated the Midnight mine and mill continuously 6 days a week in 1942. The mine produced 9,000 tons of ore, which was treated in the company 50-ton flotation mill. The products were lead-silver concentrates (sold to the Leadville smelter) and zinc concentrates (shipped to the Amarillo (Tex.) zinc smelter). D. P. Rohlfing continued to ship to the Leadville smelter lime fluxing material carrying silver and lead from the Spar lode, Aspen, and other groups under his management. Small tonnages of crude smelting ore were shipped to the Leadville smelter from the Dorothy Louise, Mt. Ranger, and Unexpected claims.

RIO GRANDE COUNTY

Summitville district.—Summitville Consolidated Mines, Inc., operated the consolidated group of mines and 150-ton mill at Summitville continuously until August 1, 1942, when it relinquished its lease on the property. On the same day the Gold Links Mine obtained a lease to continue operating the property and maintained production throughout the remainder of the year. Crude ore milled by both operators totaled 14,970 tons, from which—in addition to amalgamation bullion and cyanide precipitates—975 tons of dry gold concentrates were made containing 3,528 ounces of gold, 5,638 ounces of silver, and 96,983 pounds of copper. Ore treatment by the Summitville operation is described under the corresponding chapter and district, Minerals Yearbook, 1941. Until November 15 the Gold Links operation was entirely amalgamation; the crude ore was run through the stamps and over amalgamation plates to remove any free gold. Amalgamation tailings were tabled and concentrates filtered and shipped to the Leadville smelter. Amalgam bullion produced was shipped to the Denver Mint. On November 15, 1942, the gradual conversion to a straight flotation mill in place of the former cyanide and amalgamation treatment was completed, and production of flotation concentrates was commenced.

ROUTT COUNTY

Milbank Franz shipped to a custom mill in Utah 19 tons of zinc-lead ore containing 0.36 ounce of gold, 398 ounces of silver, 187 pounds of copper, 877 pounds of lead, and 6,407 pounds of zinc from the Greenville mine in the Hahns Peak area.

SAGUACHE COUNTY

Kerber Creek district (*Bonanza*).—The Pratt-Bonanza Mining & Milling Co. worked the St. Louis mine under lease throughout the year and shipped lead smelting ore to the Leadville smelter and the Tooele (Utah) slag-fuming plant, zinc-lead smelting ore to the Coffeyville (Kans.) pigment plant, and zinc-lead milling ore to the Combined Metals Reduction Co. custom mill at Bauer, Utah, and the custom concentrator at Midvale, Utah. A test run of 1,077 tons of St. Louis ore was made in the 50-ton flotation mill of the Flagstaff

Digitized by Google

Mining & Milling Co.; results were unsatisfactory. Regular shipments of zinc-lead ore were made to the custom mill at Bauer, Utah, and the custom concentrator at Midvale, Utah, from the Erie mine, operated throughout 1942 by Pickering and Olive Mines. Milling ore shipped averaged 12.6 ounces per ton of silver, 13.06 percent lead, 19.98 percent zinc, and a low content per ton of gold and copper. A substantial tonnage of lead ore containing 25.59 ounces per ton of silver, 19.15 percent lead, and minor quantities of gold and copper was shipped to the Leadville smelter. Lessees on the Rawley No. 1 mine and dump shipped some lead-silver-copper-gold ore to the Leadville smelter. Other shippers of crude smelting ore and milling ore included the Cora Group, Now What, and Minnie Lynch.

SAN JUAN COUNTY

Animas district.—The Shenandoah-Dives Mining Co. continued operations throughout 1942 at its consolidated group of claims on King Solomon Mountain and the Silver Lake group as a single unit, and its 750-ton selective-flotation mill on Animas River near Silverton. The mill treated 168,772 tons of ore from company mines and 2,920 tons of custom ore from other mines in San Juan County. Output from the mill totaled 4,509 tons of combined lead-copper, zinc, and iron (lead) concentrates containing in all 15,090 ounces of gold, 269,589 ounces of silver, 606,070 pounds of copper (wet assay), 2,406,020 pounds of lead (wet assay), and 961,168 pounds of zinc; the lead-copper and iron (lead) concentrates were shipped to the Leadville smelter, and the zinc concentrates (494 tons of 55.4-percent zinc content, with also gold, silver, lead, and minor copper content) to the Amarillo (Tex.) smelter. Custom ore came from the Little Fannie, Brewery tunnel, Little Nation, and Buffalo Boy mines in the Animas district; the Mountain Queen mine in the Eureka district; and the Bandora mine in the Ice Lake district. In 1942 the company entered into a 15-year contract to operate the American Smelting & Refining Co. Silver Lake unit. Ore milled in 1942 from the Silver Lake totaled 20,240 tons (included in the 168,772 tons above) assaying 0.086 ounce of gold and 1.56 ounces of silver per ton, 0.58 percent lead, 0.33 percent copper, and 0.49 percent zinc, from which 355 tons of concentrates (calculated on basis of mill recoveries) were produced. The calculated concentrates (combined lead, zinc, and iron) averaged 4.12 ounces of gold and 59.67 ounces of silver to the ton, 19.8 percent lead, 15.5 percent copper, and 15.0 percent zinc. Development in 1942 at the Silver Lake and Shenandoah-Dives groups consisted of 1,819 feet of drifts and crosscuts, 470 feet of raises, and 113 feet of diamond drilling. The Highland Mary mine and 70-ton flotation mill were operated from June 1 to November 28, 1942, when operations ceased for lack of water for the mill. The concentrates produced (containing gold, silver, copper, and lead) were shipped to the Leadville smelter. The Denver Equipment Co., agent for the Pride of the West Mining Co., operated the 100-ton Pride of the West selective-flotation mill at Howardsville continuously in 1942 on company lead-zinc-gold-silver-copper ore from the Pride of the West group. Lead concentrates (containing gold, silver, copper, and some zinc) were shipped to the Leadville smelter; zinc concentrates were shipped to the Amarillo (Tex.) smelter. Development in 1942 consisted of 1,041 feet of drifts; the capacity of the mill was increased from 70 tons to 100. Crude

Digitized by Google

lead ore was shipped to the Leadville smelter in 1942 from the Action, Austria tunnel, and Galena Champion claims; several carloads of dry gold smelting ore were shipped from the Golden Eagle property.

Eureka district.—Most of the ore produced from the mines in the Eureka district in 1942 came from the Mountain Queen claim 18 miles north of Silverton and was sold to the Shenandoah-Dives mill. About 1 car of zinc-lead ore was shipped from the Columbus property to the custom mill at Bauer, Utah. A small tonnage of zinc-lead ore recovered in development was shipped from the Mazeppa claim to the Midvale (Utah) custom mill.

Ice Lake Basin district.—The only output from the Ice Lake Basin district in 1942 was 49 tons of zinc-lead ore shipped to the Shenandoah-Dives mill and 19 tons of lead ore shipped to the Leadville smelter, all from the Bandora mine. The operators received a Reconstruction Finance Corporation Class A loan in 1942.

SAN MIGUEL COUNTY

Iron Springs district (Ophir).—All the output of the Iron Springs district in 1942 was contained in small tonnages of lead-silver ore shipped to the Leadville smelter from the Butterfly-Terrible-Silver Bell group and San Bernardo.

Upper San Miguel district (Telluride).—Telluride Mines, Inc., operated its 550-ton amalgamation and gravity- and flotation-concentration mill at Pandora 2½ miles east of Telluride and treated 146,211 tons in 1942 compared with 193,768 tons in 1941. The ore treated in 1942 was from the Smuggler Union, Pandora, Hermit, Montana, and Cimarron mines and the Adit and Marshall Basin dumps. Of the 14,556 tons of concentrates produced, 12,002 tons were lead concentrates shipped to the Leadville smelter; zinc concentrates were shipped to the Amarillo (Tex.) smelter. Gold bullion was also produced by amalgamation and shipped to the Denver Mint. Mine development in 1942 comprised 1,730 feet of drifts. Early in the year a unit of flotation cells was added to the mill circuit for the recovery of zinc. Alta Mines, Inc., operated the Alta-St. Louis group and 100-ton gravity- and flotation-concentration mill throughout 1942, but with some idleness due to lack of men, and produced 32,683 tons of ore yielding 3,307 tons of lead concentrates shipped to the Leadville smelter, containing 2,613 ounces of gold, 110,558 ounces of silver, 98,453 pounds of copper, 1,148,474 pounds of lead, and 435,966 pounds of zinc.

A war minerals study of the Black Bear mine by the Bureau of Mines resulted in the Metals Reserve Co. taking a 5-year lease on the property. The lease was signed June 11, 1943. The property will be opened by extension of the Treasury tunnel (Red Mountain, Ouray County).

SUMMIT COUNTY

Breckenridge district.—Small-scale operations only were carried on at lode mines in the Breckenridge district in 1942, and most of the ore produced was shipped direct to the Leadville smelter. Shippers included the Bemrose lode, Estella Agnes, Jumbo, Royal Tiger group, and Brooks-Snyder lode.

The Blue River Co. operated its floating connected-bucket dredge at Breckenridge from May to October 1942; later the dredge was

Digitized by Google

dismantled and equipment sold. The Bemrose-Bostwick in Hoosier Gulch and the John Jay group in French Gulch were worked by hydraulicking and sluicing. Testing of placer gravels in Nigger Gulch and on the Blue River and Little Pittsburg Creek recovered small amounts of gold, which were sold to the Denver Mint.

Green Mountain district.—Walter McDaniel continued producing zinc-silver-lead-gold-copper ore of very high zinc content from his Big Four mine on Green Mountain 17 miles south of Kremmling. Output for 1942 was 387 tons of ore (shipped to the Midvale (Utah) custom mill) containing 357,997 pounds of zinc, 2,659 ounces of silver, 8,570 pounds of lead, 6.44 ounces of gold, and 1,833 pounds of copper.

Montezuma district.—The Plymouth Milling Co. worked the New York, Waterloo, and Silver King mines and 125-ton electric-powered selective flotation mill part of 1942 and produced 47 tons of lead concentrates and 63 tons of zinc concentrates which were shipped, respectively, to the Leadville and Amarillo (Tex.) smelters. A lessee on the Fisherman group operated from January 2 until September 30 and shipped to the Midvale (Utah) custom mill 179 tons of zinc-lead ore containing 5 ounces of gold, 725 ounces of silver, 37,247 pounds of lead, and 56,721 pounds of zinc. Twenty tons of lead-silver smelting ore were shipped to the Leadville smelter. Small-scale operations on the Pinacle claim produced 73 tons of crude lead-silver-copper smelting ore, which were shipped to the Leadville smelter. A few lots of lead-silver smelting ore were also shipped from the Alvi No. 1, Quail, Erickson, Maid of Orleans, and Pennsylvania claims. Mining activities in this district in 1942 were encouraged by various loans totaling $94,000 from the Reconstruction Finance Corporation and examination of several properties by Federal Bureau of Mines engineers.

Ten Mile (Kokomo, Robinson) district.—The Wilfley Leasing Co. began production in November at its Wilfley mine and 75-ton selective flotation mill 1 mile west of Kokomo. The mill handled 799 tons of ore in 1942, composed largely of marmatite and pyrite, yielding 9 tons of lead concentrates and 128 tons of zinc concentrates which were shipped to the Leadville and Amarillo (Tex.) smelters. The opening of the property and the building of the mill were stimulated by the granting of a $71,000 loan from the Reconstruction Finance Corporation and the construction (by the Forest Service) of a 14-foot graded access road from Kokomo to the mill. L. J. Gould and A. R. Rhine operated the Washington and Hancock group (known as the Lucky Strike group) throughout 1942 and shipped 7,820 tons of zinc-lead-silver-copper-gold ore to the Midvale (Utah) custom concentrator. Crude lead-silver smelting ore shipped to the Leadville smelter totaled 74 tons.

TELLER COUNTY

CRIPPLE CREEK DISTRICT

Except for several years, Cripple Creek has been annually the leading gold-producing district in Colorado, and its total output makes it rank first among gold-producing districts. From 1891, when gold was discovered in that area, through 1942 it has yielded a total of 18,420,744 fine ounces valued at $398,300,522, or 48 percent of the State total output of gold from 1858 to 1942, inclusive. In 1942 the district produced 104,455 ounces (39 percent of the State total) compared with

Digitized by Google

133,470 ounces (35 percent) in 1941 and 128,932 ounces (35 percent) in 1940. Several factors were responsible for the decreased output in 1942, namely: Government priority restrictions regarding materials essential to mines and mills became exceedingly severe early in 1942 and have grown steadily more complicated; Selective Service regulations and attractive salaries offered by war industries created a drastic shortage of able-bodied men; the cost of labor and of mining and milling supplies increased greatly in 1942, whereas the price of gold remained fixed; and War Production Board Gold Mining Limitation Order L–208, issued October 8, 1942, has caused many mines to close. The total output of ore from Cripple Creek mines and dumps in 1942 was 377,995 tons, of which 362,460 tons were shipped to the Golden Cycle mill (operations reviewed under El Paso County). The only ore milled locally was 15,509 tons treated in the flotation mill of the Cameron Gold Mines, Inc. Cripple Creek ores generally contain gold as the only commercial metal, but some silver ore has been shipped from two or three veins in the district; a small quantity of silver is recovered annually in bullion and concentrates produced from the gold ores.

MINES REVIEW

Operations of the Golden Cycle Corporation, which owns and operates the Golden Cycle mill at Colorado Springs and several mines in the Cripple Creek district, are described in the following extract from its annual report to stockholders for the year ended December 31, 1942 (dated March 20, 1943):

During 1942 the Cripple Creek district shipped to the Golden Cycle mill 362,460 tons of ore with a gross [settlement] value of $3,607,744.94 and an average value of $9.95 per ton. This compares with 484,702 tons with a gross value of $4,640,419.99 and an average value of $9.57 per ton for 1941. This large drop in tonnage was due wholly to economic conditions brought on by the war.

The United Gold Mines Co. was still the largest producer in the Cripple Creek district with the Cresson Consolidated Gold Mining & Milling Co. second and the Golden Cycle Mining Operations third. These three properties accounted for 72 percent of the ore shipped from the district and, as in previous years, lessees operating throughout the district accounted for more than 80 percent of the total tonnage to the mill.

A large number of the company men and lessees throughout the district are older men or men who cannot get work in any other industry. The Cripple Creek district is about cleared out of younger men. The Army and Navy have received a large number of men from this district. Over forty are in the Army and Navy from the Cresson Mine alone. This labor condition affects lessees as well as the company with the result that tonnage to the mill will be greatly decreased until the war is over.

Ajax operation.—The Ajax mine during 1942 shipped a total of 29,822 tons of ore with a gross [settlement] value of $505,557.09 and an average value of $16.95 per ton. The shaft was sunk an additional 105 feet to the 28th level in March. This makes the shaft 2,900 feet deep. It still has 260 feet to go to reach the level of the Carlton tunnel. The 27th and 28th level stations were cut and crosscuts started west for the various vein systems. Due to the shortage of labor, work on both of the crosscuts has been stopped and it is doubtful if much work on these levels can be done until after the war. Most of the work at the present time is being carried on the 23d, 24th and 26th levels. The following is a summary of the development work for 1942:

	Feet
Company	3,148
Lessees	2,037
Shaft sinking	105
Total	5,290

Digitized by Google

Anchoria Leland operations.—The Anchoria Leland shipped 8,358 tons of ore with a gross value of $65,170.42 and an average value of $7.80 per ton. Practically all work done on the property during the past year was by lessees. 1,203 feet of development work was accomplished during the past year.

Index operation.—No underground work was carried out on this property during the past year. Lessees shipped 3,345 tons of dump ore with an average value of $4.93 per ton.

Carlton tunnel operation.—The only work done by the Golden Cycle Corporation on the Carlton tunnel during the past year was maintenance and salvage work. It was necessary to replace some timber and repair some track in order to keep the tunnel open. The Portland shaft was connected to the tunnel level by the United Gold Mines Co. and a large station cut on the tunnel level. The skips in Portland No. 2 shaft now run directly to the tunnel level. No work is contemplated in the tunnel until after the war. The Cresson Consolidated Gold Mining & Milling Co. and the United Gold Mines Co. then plan on driving two laterals; one of about 4,000 feet to the Cresson shaft and one of 5,000 feet to the Vindicator shaft. The flow of water from the tunnel has held steadily to about 5,400 gallons per minute throughout the year. It is well to point out at this time that a large percentage of all mine ore being shipped to the mill from the Cripple Creek district at this time has been made available by the Carlton tunnel. Without the drainage afforded by the Carlton tunnel, there would be no ore coming from the Ajax and Portland and very little from the Cresson. It is even doubtful if these properties could operate at all under present conditions.

The annual report of the United Gold Mines Co., an operating and holding company for property scattered throughout the Cripple Creek district, for the year ended December 31, 1942 (dated February 15, 1943), gives the following details on operations at individual mines:

GENERAL MANAGER'S REPORT

Production by the company and lessees was 119,346 tons, with an average value of $8.44 per ton and a gross [settlement] value of $1,007,693. Of this amount the company accounted for 21,007 tons with an average value of $6.68 per ton and a gross value of $140,314, while the lessees accounted for 98,339 tons with an average value of $8.82 per ton and a gross value of $867,379.

The Portland No. 1 and No. 2 shafts, the Vindicator, and the Rose Nicol shafts were operated by the company, largely for the accommodation of split-check lessees.

The shortage of company men and lessees has steadily grown worse throughout the year. The big blow came with the War Production Board's order closing all gold mines in October 1942. While this order was later modified, nevertheless it caused a regular exodus from this district to various defense plants, base metal mines, and other industries of a like nature, until at the present time we are left with older men or men who are not capable of doing any work except leasing in this district. In January 1942 there were 489 men working on the various properties of the United Gold Mines Co.; January 1943 shows 100 men working on these same properties. This gives some idea how employment has dropped off in this district.

The Portland No. 2 shaft was completed to the [Carlton] tunnel level and a 50-foot sump sunk below this level during the year. A large station was cut in order to handle the muck from all future work at the Carlton tunnel level. Part of the equipment, which was located at the mouth of the tunnel, has now been moved onto this station in preparation for driving both the Cresson and Vindicator laterals of the tunnel when we have the available manpower and this will not be until after the war.

Both the Portland No. 1 and No. 2 shafts were operated on company account; No. 1 shaft for the accommodation of split-check lessees, and No. 2 shaft mainly for company work. A large amount of clean-up and repair work was carried out in the lower levels of No. 2 shaft. The 31st, or the old winze level, was connected through to the shaft and a station cut. Track and pipe have been installed on this level, in preparation to do some development work when the necessary manpower is available. Considerable development work was accomplished both by the company and lessees. The company opened several small chutes of ore on the 27th and 29th levels and these are being mined to a limited extent at the present time. A considerable tonnage of low-grade ore was hoisted from a large cave on the 27th level. In fact, more ore was shipped on company account from the Portland during 1942 than for a good many years past.

Digitized by Google

There are six sets of lessees working underground on the Portland and three sets of dump lessees. All of these made a fair production during the year.

The Vindicator-Cycle group.—The Vindicator shaft was operated by the company throughout the entire year. There are seven sets of lessees operating underground on this property at the present time. The Theresa and Hull City shafts were closed down about the middle of the year, due to a lack of lessees. During the year the Vindicator sold a total of 32,212 tons of crushed rock. This was the best year we have had as far as the crushed rock business is concerned in a number of years.

Rose Nicol.—The Rose Nicol shaft produced 13,316 tons with a gross value of $163,134. Of this amount the lessees produced 8,667 tons with a gross value of $136,154, and the company accounted for the balance of 4,649 tons with a gross value of $26,980.

In spite of the shortage of both company men and lessees, the company accomplished 1,100 feet of development work and the lessees accounted for 1,145 feet, making a total of 2,245 feet on the property for the year. Some good ore was opened which is now being mined. There are seven sets of lessees operating through the Rose Nicol shaft and one set through the Trail tunnel.

Shurtloff-Findley.—This property, which had been under lease to the Golden Conqueror Mines, Inc., for a number of years, was closed down in December, due chiefly to the labor shortage. In previous years a good production came from this mine.

The Wild Horse, Deadwood, and other miscellaneous properties are all idle and there is very little chance that any work can be done on them until after the war. The Tennessee Mines Co. is operating the Patti Rosa shaft and making some production. One set of lessees are also working on the Kalamazoo. There are not more than ten men working on all the miscellaneous United Gold Mines properties. Two years ago there were probably 250 men working on this same ground.

The Teller County Air Co., which the United Gold Mines Co. owns, has virtually lost all its business since its chief market for compressed air was the small scattered operations throughout the district.

Production of company ore by United Gold Mines Co. in 1942

Mine	Net tons	Gross value [1]	Company ore cash receipts	Average gross value per ton [1]
Vindicator	2,442	$11,399	$4,058	$4.67

The annual report of the Cresson Consolidated Gold Mining & Milling Co. for the 12 months ended December 31, 1942 (dated February 1, 1943) says—

PRESIDENT'S REPORT

Herewith is annual statement of The Cresson Consolidated Gold Mining & Milling Co. for the twelve months ended December 31, 1942.

Operating gain for 1942 was $55,754, compared to $122,903 in 1941, a decrease of $67,149. Many factors, chief of which are hereafter set out, caused the large decrease in gain for 1942 compared to 1941.

Company ore produced during 1942 had a gross value of $246,596 and an average per ton gross value of $6.18, compared to a total gross value of $363,821 in 1941, with an average per ton gross value of $6.84.

Ore produced by lessees operating under split-check and royalty leases for 1942 had a gross value of $765,573 and an average per ton value of $12.48, compared to 1941 with a total gross value of $973,659 and an average per ton gross value of $12.65.

Total gross value of all ores produced by both the company and lessees during 1942 was $1,012,169, compared to $1,337,480 in 1941, a decrease of $325,311.

Early in 1942 the priority restrictions insofar as securing materials necessary for gold mining became exceedingly severe and have grown steadily worse. On October 8, 1942, the Mining Branch of the War Production Board, Washington, D. C., issued an order closing down all "nonessential" gold mines in the United States, its territories, or possessions.

SUPERINTENDENT'S REPORT

The following is a summary of the development work for twelve months, ending December 31, 1942:

Development

	Feet	*Feet*
Drifts and crosscuts:		
Company	1,707	
Hart group	233	
Lessees	1,317	
		3,257
Raises and winzes:		
Company	363	
Lessees	1,171	
		1,534
		4,791

Shortage of men during the past year resulted in the smallest production from the mine in a number of years. From the beginning of the year, labor shortage became progressively worse, reaching its climax when the War Production Board issued the order closing all gold mines. The bottom then dropped out of our man power. While the order was modified early in December just before the date set for a complete close down, the damage had been done and we were left with a small number of older men and lessees; the cream of our man power having left for various other industries paying much higher wages than it is possible for us to pay. The armed forces have also taken over forty of our younger men.

During the past year, the nineteenth level, which was under water until the later part of 1941, was cleaned up. Track and pipe lines were installed and some development work accomplished. Two bodies of medium grade ore were

Digitized by Google

opened which we are mining at the present time. Some development work was also done on various other levels of the mine and some small bodies of ore were opened.

There are eighteen sets of split-check lessees working through the Cresson shaft; however, these lessees have about fifty percent of the men which would be normally employed on these blocks of ground. Most of these lessees produced during the past year a good tonnage of ore considering the handicap they were forced to work under. One of the most serious aspects of the shortage of men by the Company and lessees is the lack of development work. At the present time we are doing less work of this kind than at any time in the history of the mine. Development work is very necessary in order to open up new bodies of ore upon which the mine must depend for its future production.

The Gold Sovereign shaft was closed down in August of this year, due to a lack of lessees. This shaft had been worked entirely by split-check lessees.

Work on the Hart group on Bull Hill, which we were carrying on through the Empire State shaft of the Empire Lee Mining Co., was also suspended during the early summer. There is much more work that should be done upon this piece of ground when conditions permit.

The water level in the Cresson shaft is now sixty-five feet below the nineteenth level, and according to the present rate of drainage, it will be at least eighteen months before it would reach the twentieth level or the bottom level of the mine. The twentieth level is 700 feet above the level of the Carlton tunnel; but as I stated in last year's report, it will be necessary to drive a lateral from the Carlton tunnel into the ground in order to give complete drainage in the Cresson property. We had planned to start this lateral during the past year but this was impossible due to the shortage of labor.

The average cost per ton shipped by company and the lessees during 1942 was $3.1177 on a total of 101,203 tons.

Production of Cresson Consolidated Gold Mining & Milling Co., 1903 to December 31, 1942

Period	Dry short tons	Gross value [1]	Freight and treatment	Net value
1903 to Dec. 31, 1941	3,093,175	$45,178,653	$14,830,495	$30,348,159
1942:				
Company ore	39,872	246,596	129,246	117,350
Lessee ore	61,331	765,573	286,947	478,625
1903 to Dec. 31, 1942	3,194,378	46,190,822	15,246,688	30,944,134

Period	Royalties received by company	Amount paid lessees	Average gross value per ton	Average net value per ton	Dividends
1903 to Dec. 31, 1941			$14.61	$9.81	$13,479,273
1942:					
Company ore			6.18	2.94	73,200
Lessee ore	$245,556	$233,070	12.48	7.80	
1903 to Dec. 31, 1942			14.46	9.69	[2] 13,552,473

[1] Settlement value.
[2] Represents 29.34 percent of gross value and 43.80 percent of net value.

Shipments from the Stratton properties in 1942 totaled 23,714 tons of ore, which had a total gross settlement value of $325,781.11 or an average settlement value of $13.74 per ton. Most of the ore was mined by lessees under the split-check system. About half of the ore produced was dump ore shipped by the Regain Corporation from three groups of dumps on Bull Hill. The principal producers of mine ore were the Alie Bell Mining Co., A. B. Cobb, Longfellow Mining Co., Jess Vetter, and J. E. Vanderwalker.

Cameron Gold Mines, Inc., operated its group of mines and 100-ton flotation mill until June 1942, when operations ceased and the corporation started liquidation proceedings. Ore treated totaled 15,509 tons yielding 702 tons of concentrates containing 1,698 ounces of gold and 1,132 ounces of silver; the concentrates were shipped to the Leadville smelter. In approximate order of gold output the Empire Lee, Acacia, Free Coinage, Forest Queen, and Jerry Johnson continued to be important producers in 1942 until December 10. Some of the other producing mines and dumps were the Black Belle, Cardinal-Great West, Dr. Jack Pot, Economic dump, Joe Dandy, New Gold Dollar, and Strong.

SUMMARY

The principal copper, zinc, and zinc-lead mines in the Eastern States operated at or near capacity throughout 1942, and their total output of copper and zinc increased over 1941. Zinc production in New York and Tennessee and byproduct copper production from the Cornwall iron mine in Pennsylvania were larger than in any previous year. Copper production increased in Tennessee also but decreased in North Carolina. The output of zinc in New Jersey—second-largest zinc-producing State in the United States during the year—was nearly the same as in 1941, and that in Virginia decreased. Although fixed or ceiling prices on copper, lead, and zinc prevailed throughout 1942, the Government premium-price program, effective February 1, and funds obtainable through Federal lending agencies provided incentives for expansion in mining, development, and prospecting. An old zinc-lead mine in Virginia was reopened during the year, and a newly developed zinc mine in Tennessee and an old copper mine in Vermont were being equipped and prepared for operation as the year ended. Gold production in the Eastern States decreased heavily. Two mines, one in North Carolina and one in South Carolina, yielded 77 percent of the total in 1942 and 83 percent in 1941. Both these mines suspended operations before the end of October 1942, and nearly all the gold output during the last 2 months of the year (averaging 218 ounces monthly) was incident to the mining of iron and copper. Small lode and placer mines exempted from Gold Mining Limitation Order L–208 issued by the War Production Board on October 8, 1942, produced only 3 percent of the total gold output of the Eastern States in 1941 and 4 percent in 1942. The lead output in both years came from mines producing zinc as the metal of chief value, and the silver production was that recovered as a byproduct of the mining of other metals.

Digitized by Google

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported, except that of zinc in New Jersey, has been calculated at the following prices. The value of the New Jersey production is the total value of the zinc recoverable as metal and oxide after freight, haulage, smelting, and manufacturing charges are added.

Prices of gold, silver, copper, lead, and zinc, 1938–42

Year	Gold [1]	Silver [2]	Copper [3]	Lead [4]	Zinc [4]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1938	$35.00	[5] $0.646+	$0.098	$0.046	$0.048
1939	35.00	[6] .678+	.104	.047	.052
1940	35.00	[7] .711+	.113	.050	.063
1941	35.00	[7] .711+	.118	.057	.075
1942	35.00	[7] .711+	.121	.067	.093

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.
[2] Treasury buying price for newly mined silver.
[3] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production but excludes value of foreign copper delivered to Metals Reserve Co. for domestic consumption.
[4] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production.
[5] $0.64646464. [6] $0.67878787. [7] $0.71111111.

Annual figures for the 5 years ended with 1942 are given in the table that follows. The figures for tonnage of ore sold or treated do not include magnetite ore containing pyrite and chalcopyrite, from which copper, gold, and silver were recovered as byproducts.

Mine production of gold, silver, copper, lead, and zinc in the Eastern States, 1938–42, in terms of recovered metals

Year	Mines producing		Ore sold or treated (short tons) [1]	Gold (lode and placer) [2]		Silver (lode and placer) [3]	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1938	51	26	3,159,880	19,928	$697,480	94,945	$61,380
1939	47	24	3,409,619	17,414	609,490	94,083	63,862
1940	40	18	3,674,815	18,456	645,960	102,825	73,120
1941	43	14	3,780,397	21,982	769,370	106,051	75,414
1942	36	17	4,166,226	14,699	514,465	105,307	74,885

Year	Copper		Lead		Zinc		Total value
	Pounds	Value	Short tons	Value	Short tons	Value	
1938	21,079,160	$2,065,758	7,900	$726,800	172,501	$19,211,235	$22,762,653
1939	21,295,000	2,214,680	6,284	590,696	180,955	21,100,174	24,578,902
1940	25,490,000	2,880,370	4,831	483,100	178,815	24,135,445	28,217,995
1941	27,132,000	3,201,576	5,513	628,482	191,310	29,484,423	34,159,265
1942	28,404,000	3,436,884	4,475	599,050	199,809	36,190,180	40,816,064

[1] Excludes magnetite-pyrite-chalcopyrite ore from Pennsylvania.
[2] Includes placer gold as follows—1938: 667 ounces; 1939: 413 ounces; 1940: 452 ounces; 1941: 203 ounces; 1942: 69 ounces.
[3] Placer silver did not exceed 39 ounces in any year during the 5-year period.

Digitized by Google

Gold.—The old Haile mine in Lancaster County, S. C., near Kershaw (operated only 9 months in 1942) yielded 50 percent of the total mine output of gold in the Eastern States in 1942 and 69 percent in 1941. The Condor mine near Waxhaw, Union County, N. C.—second-largest producer of gold in both years—contributed 27 percent of the total in 1942 and 14 percent in 1941; the mine was closed in October 1942. The only other important producer of gold in 1942 was the Cornwall mine in Lebanon County, Pa., which yields gold, silver, and copper as a byproduct of iron mining. Changes in output of gold in the various States in 1942 comprised increases of 833 ounces in North Carolina and 77 ounces in Pennsylvania and decreases of 7,684 ounces in South Carolina, 281 ounces in Georgia, 131 ounces in Virginia, 68 ounces in Tennessee, and 29 ounces in Alabama. The estimated output of gold in the Southern Appalachian States from 1799 to 1942 is recorded as follows:

Mine production of gold in the Southern Appalachian States, 1799–1942

State	Period	Fine ounces	Value	State	Period	Fine ounces	Value
Alabama	1830–1942	49,489	$1,198,775	South Carolina	1829–1942	318,654	$7,556,980
Georgia	1830–1942	870,509	18,083,662	Tennessee	1831–1942	20,197	454,525
Maryland	(1) –1942	6,102	163,940	Virginia	1828–1942	167,364	3,570,719
North Carolina	1799–1942	1,164,436	24,322,523	Total	1799–1942	2,596,751	55,351,124

[1] Year of first production not recorded.

Silver.—The silver recovered from ores and gravels mined in the Eastern States in 1942 comprised 55,926 ounces derived from copper and iron (magnetite-pyrite-chalcopyrite) ores, 41,773 ounces from zinc-lead ores, 7,606 ounces from gold ores, and 2 ounces from placer gravel.

Copper.—The upward trend in copper production in the Eastern States which began in 1939 continued in 1942, when the output increased 5 percent over 1941 and was 35 percent above that in 1938. The quantity of copper recovered in 1942 from magnetite-pyrite-chalcopyrite ore of the Cornwall mine in Pennsylvania was the highest annual output to date, and that recovered from copper ore increased slightly. As the three mines that produced nearly all the copper output of the Eastern States in 1942 are in different States (North Carolina, Pennsylvania, and Tennessee), it is not possible to show the production separately by States without disclosing that of each mine; the combined output of the three States is shown under Tennessee in the following table. Copper ore yielded, in recovered metals, about 0.0003 ounce of gold and 0.05 ounce of silver to the ton of crude ore. Copper concentrates from the Cornwall ore contained some recoverable gold and silver.

Lead.—The mine output of recoverable lead in the Eastern States was 4,475 tons in 1942 compared with 5,513 tons in 1941. The figures for 1941 include some lead contained in concentrates shipped from mine stocks accumulated in previous years, whereas those for 1942 represent the recoverable metal in concentrates actually produced during the year. Comparing actual mine production in 1941 (4,039 tons) with that in 1942 shows an increase for 1942 of 11 percent.

Digitized by Google

Zinc-lead sulfide ores from the Austinville mine in Virginia and the Balmat in New York continued to yield the bulk of the lead output; the rest came from lead carbonate ore from the Embree mine (producing also zinc carbonate), mixed zinc-lead carbonate and sulfide ore from the Bunche's Hollow (Imperial) in Tennessee, and zinc-lead sulfide ore from the Valzinco in Virginia.

Zinc.—Zinc mine operators in the Eastern States made determined efforts to obtain maximum production from developed ore reserves in 1942 and to find and develop ore bodies upon which to draw to help meet the anticipated continued heavy demand for zinc for the duration of the war. Several of the mines made the largest annual production in the history of their operation, and the Eastern States total output of recoverable zinc was the largest on record—199,809 tons in 1942 compared with 191,310 tons in 1941. The figures for 1941 include some zinc contained in concentrates shipped from mine stocks accumulated in previous years, whereas those for 1942 represent the recoverable metal in concentrates actually produced during the year. Comparing actual mine production in 1941 (186,880 tons) with that in 1942 shows a 7-percent increase for 1942. The output in New York increased 19 percent and in Tennessee 22 percent; in New Jersey it varied little from 1941 (0.28 percent increase); and in Virginia actual production (not shipments) decreased 13 percent. About 95 percent of the total zinc output in the Eastern States in 1942 was produced without benefit of the Government premium. It is unlikely that this high percentage can be maintained in 1943 if the 8.25-cent ceiling price remains unchanged. The developed high-grade ore bodies are being depleted at a rapid rate, necessitating much new prospect drilling and mine development, as well as the mining of lower-grade ores. Increases in production costs thus incurred, which cannot be absorbed by the mining companies, probably will be compensated by quota adjustments. Also, production from new enterprises will be paid for at premium prices. The Valzinco zinc-lead mine in Spotsylvania County, Va., which was reopened and equipped with a 100-ton mill in 1942, began producing before the end of the year; and the American Zinc Co. of Tennessee plans to open a newly developed mine at Jefferson City, Tenn., during the first part of 1943.

[1] Ore is magnetite-pyrite-chalcopyrite, flotation copper concentrates from which yielded gold, silver, and copper; Bureau of Mines not at liberty to publish figures for ore and copper.
[2] Excludes magnetite-pyrite-chalcopyrite ore from Pennsylvania.
[3] Estimated smelting value of recoverable zinc content of ore after freight, haulage, smelting, and manufacturing charges are added.
[4] North Carolina and Pennsylvania included under Tennessee; Bureau of Mines not at liberty to publish separate figures.
[5] Excludes value of copper, which is included under Tennessee.
[6] Includes also value of copper from North Carolina and Pennsylvania.

MINING INDUSTRY

The total output of ores yielding gold, silver, copper, lead, or zinc in the Eastern States, excluding the magnetite-pyrite-chalcopyrite ore from Pennsylvania, increased 10 percent in 1942 over 1941 to 4,166,226 tons, the highest annual production in the 37-year period (1906–42) for which complete data are available. Eight large, well-equipped zinc and zinc-lead mines in New Jersey, New York, Tennessee, and Virginia and three copper-iron sulfide mines in the Ducktown (Tenn.) district together yielded 96 percent of the total ore in 1942; all were operated at a high production rate, and some were operated beyond their normal capacity to provide the maximum quantity of metals needed for war purposes. War conditions caused a general shutdown of mines producing gold ores. The copper, zinc, and zinc-lead ores of the Eastern States yield byproducts (besides gold and silver), the value of which would have to be considered to show the

Digitized by Google

full value of the crude ore mined. Copper-iron ore from Tennessee and zinc-lead-pyrite ore from New York yield pyrite concentrates that are used in the manufacture of sulfuric acid, and sulfuric acid is also made from gases produced in roasting zinc sulfide concentrates from zinc and zinc-lead ores of Tennessee, New York, and Virginia. New Jersey zinc ore yields a residue which is further treated for the recovery of other metals; and zinc ore milled in Tennessee yields a commercial tailing, some of which is sold for its lime content and some for use in concrete. The quantity of the various types of ore mined in the Eastern States is shown in the table that follows.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in the Eastern States in 1942, with content in terms of recovered metals

Source	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (short tons)	Zinc (short tons)
Dry and siliceous gold ore	106,555	11 861	7,606	1,000	----------	----------
Copper ore	843,995	260	40,425	[1] 28,351,000	----------	[3]
Magnetite-pyrite-chalcopyrite ore	[3]	2,499	15,501	[1]	----------	----------
Lead ore	4,627	----------	----------	----------	200	----------
Zinc ore	2,364,229	----------	----------	----------	----------	150,270
Zinc-lead ore	846,820	10	41,773	52,000	4,275	[2] 49,539
Total, lode mines	[4] 4,166,226	14,630	105,305	28,404,000	4,475	199,809
Total, placers	----------	69	2	----------	----------	----------
Total, 1941	[4] 4,166,226	14,699	105,307	28,404,000	4,475	199,809
	[4] 3,780,397	21,982	106,051	27,132,000	5,513	191,310

[1] Copper from magnetite-pyrite-chalcopyrite ore included with that from copper ore.
[2] Zinc from copper ore included with that from zinc-lead ore; Bureau of Mines not at liberty to publish separate figures.
[3] Bureau of Mines not at liberty to publish separate figures for ore and copper.
[4] Excludes magnetite-pyrite-chalcopyrite ore from Pennsylvania.

METALLURGIC INDUSTRY

All the principal producing base-metal mines in the Eastern States except the Fontana copper mine in North Carolina have concentrating mills at or near the mines, but a considerable tonnage of copper ore is smelted direct, and some of the crude zinc ore is shipped to oxide plants. The ore from the Fontana mine is shipped to the Tennessee Copper Co. plant in Tennessee. The methods of treatment used in the various mills and other operating details, including the tonnage and grade of concentrates produced by some of the mills, are given in the Review by States that follows. Most of the concentrates are shipped to smelters operated by the companies that own the mines. The principal development in zinc-ore concentration during the past 7 years has been the increased tonnage treated at Mascot, Tenn., by the differential-density process of gravity concentration. This process is used as the first step in concentration and discharges a large part of the crushed mine ore at a coarse size as a finished tailing, thus reducing the quantity to be treated by jigging, fine grinding, and flotation.

The methods of recovering gold and silver in the Eastern States in 1942 are shown in the following table.

Digitized by Google

Mine production of gold and silver in the Eastern States in 1942, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)
Ore and old tailings amalgamated	371	119	87
Ore cyanided	105,726	11,302	7,312
Concentrates smelted [1]	77,032	2,668	91,945
Ore smelted [1]	20,812	541	5,961
Placer		69	2
Total, 1941		14,699	105,307
		21,982	106,051

[1] Excludes material containing no recoverable gold or silver. The totals for concentrates and direct-smelting ore shipped were 703,771 and 99,296 tons, respectively.

REVIEW BY STATES

ALABAMA

A lessee at the Hog Mountain mill dump in Alabama near Alexander City, Tallapoosa County, recovered 1 ounce of gold from old tailings in 1942.

GEORGIA

There was little activity at gold mines in Georgia in 1942. Of the 30 ounces of gold produced, 15 ounces came from scattered placer mines in Cherokee and Lumpkin Counties and 15 ounces from lode mines on the Brand Estate and Dean Hole properties in Cherokee County and the Russell property in Paulding County. Seven ounces of silver were recovered from the gold bullion and retorts shipped during the year.

NEW JERSEY

Zinc production in New Jersey was approximately the same in 1942 as in 1941. The producing mines in both years were the Mine Hill and the Sterling Hill at Franklin and Ogdensburg, respectively, in Sussex County. The commercial minerals in the ore are franklinite, willemite, and zincite. Each mine is equipped with a mill. In treatment, the franklinite (an iron-manganese-zinc oxide mineral) is removed from the crushed ore by magnetic separators, and the willemite and zincite are concentrated on jigs and tables. The concentrates are shipped to company plants at Palmerton, Pa. Part of the zinc is recovered as metal and part in oxide.

The value of the New Jersey output of zinc given in the table of this chapter under the heading Mine Production by States is the combined value of the zinc recoverable in both metal and oxide after freight, haulage, smelting, and manufacturing charges are added.

New Jersey has a few deposits of copper ore, but none has been worked for many years. At Carteret and Perth Amboy are copper and lead smelters and refineries that treat ores, scrap, byproducts, and bullion from various States and foreign countries.

NEW YORK

The mine production of recoverable zinc in New York increased 19 percent in 1942 over 1941, lead 16 percent, and silver 6 percent. The silver and lead and most of the zinc came from the Balmat mine

Digitized by Google

in St. Lawrence County about 8 miles southeast of Gouverneur. This mine and the Edwards about 12 miles northeast of the Balmat are owned and operated by the St. Joseph Lead Co. The Balmat ore contains zinc, iron, and lead sulfides, and some silver is associated with the lead; it is mined through a 2,655-foot inclined shaft (vertical depth, about 1,300 feet) and treated in the selective flotation plant at the mine. The daily capacity of the mill at the end of 1942 was 1,200 tons. The mill feed in 1942 totaled 380,893 tons (44,622 tons more than in 1941); it yielded 4,165 tons of lead concentrates containing 60.23 percent lead and 10.12 ounces of silver to the ton, 62,560 tons of zinc concentrates containing 56.47 percent zinc, and 77,087 tons of pyrite concentrates containing 41.18 percent iron and 49.41 percent sulfur. The Edwards mine and flotation mill were also operated at a higher rate than in 1941. The mine has a vertical shaft to the 1,500-foot level and an inclined shaft 1,361 feet long, of which 149 feet were sunk in 1942. Ore treated totaled 151,403 tons yielding 25,229 tons of zinc concentrates containing 58.97 percent zinc. The zinc concentrates from both mills were shipped to the company electrothermic zinc-reduction plant at Josephtown, Pa. Part of the lead concentrates from the Balmat mill were shipped to the company smelter at Herculaneum, Mo., and part to the U. S. Metals Refining Co. plant at Carteret, N. J. The pyrite concentrates were sold to sulfuric acid plants. The Universal Exploration Co. operated its Hyatt zinc mine and 200-ton flotation mill near Emeryville from January to August; mining and milling were suspended the rest of the year but were resumed in February 1943. The concentrates produced were shipped to the Donora (Pa.) smelter.

Development of the zinc and lead deposits in St. Lawrence County was begun in 1911, and the State became an important producer of zinc in 1915. The following table gives the annual output of silver, lead, and zinc from 1928 to 1942.

Mine production of silver, lead, and zinc in New York, 1928–42, in terms of recovered metals [1]

Year	Ore and old tailings treated (short tons)	Silver (fine ounces)	Lead (short tons)	Zinc (short tons)	Total value
1928	125,192			11,257	$1,373,354
1929	149,183			10,250	1,353,000
1930	270,601		1,158	22,471	2,273,016
1931	269,582		1,573	24,100	1,948,002
1932	189,679		1,280	16,794	1,084,440
1933	180,670		990	17,733	1,562,532
1934	282,952	26,406	1,690	23,188	2,136,299
1935	295,179	21,750	1,285	23,720	2,205,793
1936	377,451	18,251	1,120	26,941	2,811,275
1937	464,870	41,500	2,280	32,690	4,550,840
1938	385,600	37,200	2,005	29,896	3,078,524
1939	420,000	37,250	2,387	36,014	3,995,119
1940	432,219	35,720	1,973	35,686	4,719,137
1941	488,079	37,734	2,100	38,446	6,033,133
1942	548,816	40,012	2,434	45,807	8,874,711

[1] No output of gold or copper was recorded in New York during this period.

There are no zinc or lead smelters in New York. The Phelps Dodge Refining Corporation has a custom copper smelter and an electrolytic refinery at Laurel Hill which treat copper ore, matte, bullion, and copper-bearing scrap material.

NORTH CAROLINA

Gold production in North Carolina increased 26 percent in 1942 over 1941, silver increased 11 percent, and copper decreased 10 percent. The increase in gold resulted from continuous operation from January to about October 15 of the Condor (old Howie) mine at Waxhaw in Union County, operated under lease by Hugh Jardine. This mine was reopened in 1940, and the ore produced in that year was shipped to the Capps cyanide mill at Charlotte for treatment. Operations during the first part of 1941 were confined to development work and the building of a 100-ton countercurrent cyanide mill on the property. The mill was placed in operation on July 15, 1941, and ran steadily until October 1942, when both mine and mill were closed in compliance with the Gold-Mining Limitation Order of the War Production Board. The total production in the 3 years was 42,018 tons of ore, yielding 8,967 fine ounces of gold and 6,073 fine ounces of silver valued in all (on the basis of mint returns) at $318,187. Scattered small shippers of amalgam retorts and gold dust to the Philadelphia Mint and New York Assay Office during 1942 were: Wright Mines, Inc., in Franklin County; Passavant Bros., Enfield, Halifax County; Joe Rogers, near Indian Trail, and John L. James, Charlotte, both in Mecklenburg County; and C. F. Crisson, Nebo, McDowell County.

Copper output from the Fontana copper mine in Swain County decreased in 1942. The mine is operated by the North Carolina Exploration Co., which ships the crude ore to the Tennessee Copper Co. smelter at Copperhill, Tenn. The ore contains very small quantities of gold and silver, some of which are recovered as byproducts in refining the copper bullion. E. C. McSwain sank a 40-foot shaft at a prospect on his property in Chatham County near Hemp and shipped 33 tons of copper-silver ore to the U. S. Metals Refining Co. at Carteret, N. J., and 100 tons (wet weight) to the Daugherty Chemical Co., Troy, N. C. Diamond drilling was done on the old Silver Hill property in Davidson County, which has produced zinc-lead ore containing copper, gold, and silver.

PENNSYLVANIA

The Bethlehem Steel Co. continued in 1942 to recover gold, silver, and copper as byproducts of iron mining at its Cornwall mine in Lebanon County, Pa. The mine is developed by an open pit and three inclined shafts, which had reached a depth of 1,700 feet at the end of the year. The ore minerals are magnetite, pyrite, and chalcopyrite (carrying a little gold and silver). The ore-treatment plants comprise a 6,500-ton magnetic separation plant producing iron concentrates, a 2,400-ton sintering plant for handling the iron concentrates, and a 2,800-ton flotation mill in which the tailings from the magnetic plant are concentrated to recover copper, gold, and silver. The quantity of each of these metals recovered was larger in 1942 than in 1941.

SOUTH CAROLINA

Although gold production in South Carolina declined 50 percent in 1942 from 1941, the State continued to rank first among the Eastern States in gold output. Operations at the old Haile mine

Digitized by Google

near Kershaw, which contributed the bulk of the State output from 1937 to 1942, inclusive, were suspended in September 1942, presumably for the duration of the war. The ore was mined chiefly from open pits and was treated in the 400-ton cyanide mill on the property. The total production from the mine in the 6-year period ended 1942 was 538,046 tons of ore yielding 60,013 fine ounces of gold and 27,048 fine ounces of silver having a total net value (based on mint returns) of $2,115,079. Small tonnages of gold ore containing a little silver and copper were shipped to the U. S. Metals Refining Co. smelter at Carteret, N. J., by L. M. Martin of Kings Creek and E. R. Vreeland of Smyrna. W. K. Hunter shipped 214 tons of gold ore from Hickory Grove to the Tennessee Copper Co. smelter at Copperhill, Tenn.

TENNESSEE

Zinc production (in terms of recovered metal) in Tennessee in 1942 totaled 43,971 tons and exceeded the previous record annual output of 1941 by 7,801 tons. The output of recovered copper and lead also increased, but that of gold and silver decreased. The gold and silver and some of the zinc were byproducts of the copper-iron mining, milling, and smelting operations of the Tennessee Copper Co. at Ducktown and Copperhill in Polk County. Important commercial products derived from the copper-iron ores (besides copper bullion and zinc concentrates) included sulfuric acid and copper sulfate manufactured in the company plants and iron sinter sold to iron and steel producers, mostly in the Birmingham (Ala.) district. The zinc concentrates produced in the mills were sold to the Donora (Pa.) smelter. The copper-iron sulfide concentrates and direct-smelting crude ore were treated in the company Copperhill smelter, which also treated copper-iron sulfide ore from the Fontana mine in Swain County, N. C. The crude copper ore is treated in the reverberatory furnace, yielding matte which is sent to the converter. The concentrates are fed directly into the converter. Most of the blister copper from the converter is cast into pigs and shipped to an electrolytic refinery on the Atlantic seaboard, where the byproduct gold and silver are recovered. Shot copper is produced for use in the copper sulfate plant. Two blast furnaces maintained as stand-by equipment are operated when the company desires to increase production of sulfuric acid. In 1942 the company operated the Burra Burra, Eureka, and Boyd groups of mines and the London and Isabella selective flotation mills. The rated daily capacity of the mills at the end of the year was 1,450 and 1,050 tons, respectively. The ore is hoisted through vertical shafts, one of which is 2,400 feet deep. Development done in 1942 totaled 383 feet of shaft, 17,307 feet of drifts, and 14,802 feet of diamond drilling.

From 1928 to 1939, inclusive, the Bureau of Mines was not at liberty to publish separate State totals for lead and zinc production in some of the Eastern States, and the figures for those States were combined under Tennessee in the chapters of this series. As separate State totals may now be published for Tennessee and Virginia, the totals for Tennessee from 1928 to 1942 are shown in the accompanying table. Figures for Virginia are given in the following review for that State.

Mine production of lead and zinc in Tennessee, 1928–42, in short tons, in terms of recovered metals

Year	Ore [1] sold or treated	Lead	Zinc [1]	Year	Ore [1] sold or treated	Lead	Zinc [1]
1928	570, 199	---- ----	14, 597	1936	849, 833	805	23, 830
1929	682, 680	---- ----	19, 805	1937	987, 256	405	29, 335
1930	709, 760	13	22, 606	1938	909, 700	553	29, 810
1931	779, 500	215	25, 320	1939	1, 083, 900	517	32, 375
1932	631, 400	430	12, 841	1940	1, 216, 044	573	34, 796
1933	652, 820	296	21, 442	1941	1, 300, 916	23	36, 170
1934	828, 215	340	25, 972	1942	1, 560, 259	238	43, 071
1935	750, 440	190	23, 102				

[1] Ore figures exclude copper ore, from which some zinc was recovered as a byproduct each year from 1930 to 1942, inclusive. Such byproduct zinc is included in zinc figures.

Most of the zinc output of Tennessee in 1942, as in 1941, came from four mines in Knox and Jefferson Counties. Three of these—Mascot No. 2, Jarnagin, and Grasselli—were operated by the American Zinc Co. of Tennessee. The Mascot is opened by a 520-foot shaft and an inclined shaft from the 520-foot level to the maximum depth of 850 feet. The Grasselli has one operating shaft and an auxiliary manway shaft and is 350 feet deep. The Jarnagin has one operating shaft 280 feet deep, with an auxiliary manway shaft. All the mines are fully mechanized, and slushing is the principal method of loading. Development done at the three mines in 1942 totaled 5,419 feet of drifts, 8,516 feet of diamond drilling, and 25,877 feet of churn drilling. The crude ore from all three mines was treated in the company mill at the Mascot No. 2 mine at Mascot. The ore from the Grasselli and Jarnagin—12 and 16 miles, respectively, east of Mascot—was transported to the mill over the Southern Railway. The mill is equipped with a differential-density cone unit, jigs, and flotation machines. It treated 1,263,039 tons of crude ore in 1942, and its total output of zinc concentrates was 55,831 tons—a 25-percent increase over 1941. The company planned to open a fourth mine—the newly developed Carson Newman (Athletic Field) at Jefferson City—in 1943; the ore will be shipped to the Mascot mill. The other large zinc producer in 1942 was the Davis property of the Universal Exploration Co. at Jefferson City, which is equipped with an 800-ton flotation mill for treating sulfide ore and a small plant for concentrating carbonate ore. The flotation mill was operated at near capacity throughout the year, and the carbonate plant treated a small tonnage daily. The output of both sulfide and carbonate concentrates was larger than in 1941. The average grade of the blende shipped in 1942 was 64.53 percent zinc. The Embree Iron Co. produced several cars of zinc and lead carbonate concentrates monthly from April through December at its property near Embreeville, Washington County. In Claiborne County the Imperial Mining Co. operated the Bunche's Hollow mine 2 miles northwest of Goin during part of 1942; the mine is equipped with a small jig mill. Dr. Gant Gaither shipped 324 tons of 58-percent zinc concentrates from the Hoover mine 10 miles northeast of Murfreesboro; the ore was concentrated in a 4-cell jig. George Blow shipped ore from a prospect on his property in Union County to the flotation mill at the Austinville (Va.) mine.

Digitized by Google

VERMONT

In August 1942 the Vermont Copper Co., Inc., entered into a contract with the Metals Reserve Co. to reopen and reequip the Elizabeth copper mine near South Strafford, Orange County, and operate it for 2½ years. The copper produced is to be sold to the Metals Reserve Co. Construction of a 500-ton concentration mill and reequipment of the mine was begun in October. The mine had not been worked since June 1930. The ore minerals are chalcopyrite and pyrrhotite, carrying some silver.

VIRGINIA

Gold mines operating in Virginia in 1942 were the Red Bank lode mine 5 miles north of Virgilina, Halifax County, equipped with a small amalgamation mill, and the Ruth placer mine on Byrd Creek in Goochland and Fluvanna Counties, equipped with a dragline and portable washing plant; each of the mines operated about 3 months, and their combined output was 99 ounces of gold and 32 ounces of silver. Some gold and silver were recovered from zinc-lead-iron-copper-silver-gold ore from the old Valzinco mine 6 miles southeast of Paytes post office, Spotsylvania County, which was reopened during the year by Panaminas, Inc., subsidiary of Ventures, Ltd. The company built a 100-ton selective flotation mill at the mine and began treating ore in September. The products of the mill were zinc concentrates, carrying lead, copper, silver, and gold; and lead concentrates, carrying copper, zinc, silver, and gold. Several hundred tons of the zinc concentrates were shipped to the American Zinc & Chemical Co. smelter at Langeloth, Pa., in 1942.

The total output of recoverable lead in Virginia in 1942 was 1,803 tons and that of zinc 15,991 tons compared with 1,916 and 18,483 tons, respectively, in 1941. The foregoing 1941 figures for recoverable lead and zinc represent actual mine production during the year and are lower than those representing mine shipments given in Minerals Yearbook, 1941, which include 4,430 tons of zinc and 1,474 tons of lead contained in concentrates shipped from stocks accumulated before 1941 but not previously included in the annual production statistics. The bulk of the State output of lead and zinc from 1928 through 1942 came from the Austinville mine in Wythe County. In 1942 the mine operated two shifts a day, 6 days a week. The ore was treated in the 2,000-ton selective flotation mill at the mine. After April the mill also handled small tonnages monthly of purchased crude ore. The Lacy-Butler Co. shipped 708 tons of zinc carbonate ore to the smelters at Palmerton, Pa., and Meadowbrook, W. Va., from the leased Little Wythe mine at Cripple Creek, also in Wythe County.

The following table shows mine production of gold, silver, copper, lead, and zinc in Virginia, 1928–42; the Bureau of Mines has not been at liberty heretofore to show the annual figures for 1928 to 1939, inclusive.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN IDAHO

(MINE REPORT)

By G. E. Woodward and Paul Luff

SUMMARY OUTLINE

	Page		Page
Summary	363	Metallurgic industry	369
Calculation of value of metal production	363	Review by counties and districts	374
Mine production by counties	367	Coeur d'Alene region	382
Mining industry	368		
Ore classification	369		

SUMMARY

The total value of gold, silver, copper, lead, and zinc produced by Idaho mines was $46,063,326 in 1942 compared with $41,776,848 in 1941—a 10-percent increase (see fig. 1). The value of the gold output was $3,325,700 (7 percent of the State total), silver $10,414,144 (nearly 23 percent), copper $830,060 (2 percent), lead $15,263,806 (33 percent), and zinc $16,229,616 (35 percent). Production of lead in Idaho in 1942 (227,818,000 pounds) was the largest since 1930, and the output of zinc (174,512,000 pounds) was by far the greatest in any year in the history of the State. Compared with 1941 the gold output decreased nearly 37 percent, silver 12 percent, and copper 5 percent; lead increased more than 8 percent and zinc 10 percent.

The production of copper, lead, and zinc in Idaho in 1942 was affected by several factors. The Metals Reserve Co. announced that, effective February 1, 1942, premiums amounting to 5 cents a pound for copper and 2¾ cents a pound for both lead and zinc would be paid for these metals produced in excess of certain fixed basic quotas. The basic quota of each mine was fixed according to 1941 output; however, several zinc-lead producers in Idaho, particularly in the Coeur d'Alene region, could not maintain their 1941 production rate, and during the fall of 1942 lower basic production quotas were granted to certain companies. Also, effective December 1, 1942, the Metals Reserve Co. announced that it would pay an additional premium of 2¾ cents a pound for lead and two additional premiums of 2¾ cents a pound for zinc for overquota metal production.

A labor shortage began in April at the mines, mills, and smelters in Idaho, resulting from men leaving to take jobs on Government construction projects and in war industries where abnormally high wages were paid. This shortage became so acute during the summer that some mines closed and others curtailed output 50 percent. The seriousness of the condition was recognized by the War Department, which furloughed about 800 soldiers in October for service in Idaho mines. This action tended to relieve the shortage but did not insure an adequate labor supply.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of metal production herein reported has been calculated at the following prices.

Digitized by Google

Prices of gold, silver, copper, lead, and zinc, 1938–42

Year	Gold [1]	Silver [2]	Copper [3]	Lead [4]	Zinc [4]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1938	$35.00	[5] $0.646+	$0.098	$0.046	$0.048
1939	35.00	[6] .678+	.104	.047	.052
1940	35.00	[7] .711+	.113	.050	.063
1941	35.00	[7] .711+	.118	.057	.075
1942	35.00	[7] .711+	.121	.067	.093

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from Jan. 18, 1837, to Jan. 31, 1934, was $20.67+($20.671835) per fine ounce.
[2] Treasury buying price for newly mined silver.
[3] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production but excludes value of foreign copper delivered to Metals Reserve Co. for domestic consumption.
[4] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production.
[5] $0.64646464. [6] $0.67878787. [7] $0.71111111.

Mine production of gold, silver, copper, lead, and zinc in Idaho, 1938–42, and total, 1863–1942, in terms of recovered metals

Year	Mines producing		Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value

[1] A floating washing plant supplied with gravel by a dragline excavator is called a "dragline floating dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."

Gold.—The output of recoverable gold in Idaho was nearly 37 percent less in 1942 than in 1941. This decrease is attributed in part to the gold-mine closing order issued by the Government in October; but several large gold producers, both lode and placer, had shut down before the closing order was issued, owing to difficulty of obtaining labor and supplies. The yield of gold from lode mines decreased 35 percent and that from placers 38 percent. About 37 percent of the State total gold in 1942 came from siliceous gold ore and more than 45 percent from all types of dredging operations. Ten floating (bucket) dredges, 2 less than in 1941, treated 7,772,947 cubic yards of gravel and recovered 36,611 ounces of gold—a decrease of 15,747 ounces from 1941; 7 dragline dredges and 5 dry-land dredges treated 1,175,937 cubic yards of gravel and recovered 6,689 ounces of gold—a decrease of 8,221 ounces. Of the total placer gold, 91 percent came from the Boise Basin, Elk City, Gibbonsville, Hoodoo, Middle Boise, and Yankee Fork districts, where dredges were operated. Nearly half of the total lode gold came from the Middle Boise (Atlanta) district. Large decreases in output of gold were made in the Elk City, Boise Basin, Yellow Pine, Yankee Fork, Warren, and Burgdorf-Marshall Lake districts.

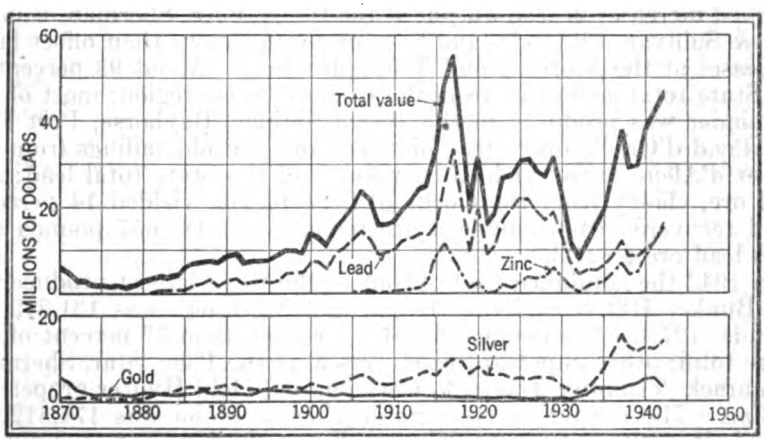

FIGURE 1.—Value of mine production of gold, silver, lead, and zinc and total value of gold, silver, copper, lead, and zinc in Idaho, 1870–1942. The value of copper has been less than $2,000,000 annually, except in a few years.

Talache Mines, Inc., operating a lode property at Atlanta, was by far the largest gold producer in Idaho. It was followed by the Fisher-Baumhoff Co., operating two bucket dredges near Centerville; Boise King Placers, operating a bucket dredge near Twin Springs; Northwest Goldfields bucket dredge near Harvard; Idaho-Canadian Dredging Co. bucket dredge at Idaho City; Snake River Mining Co., operating a bucket dredge at Sunbeam; Triumph lode mine near Ketchum; and De Lamar Milling Corporation at De Lamar.

Silver.—The output of recoverable silver in Idaho was 14,644,890 fine ounces in 1942—a 12-percent decrease from 1941. Production from the Sunshine mine, largest silver producer in the United States, declined more than 2,000,000 ounces. The Coeur d'Alene region produced nearly 89 percent of the State total silver in 1942; the rest came largely from the Warm Springs, Carson, Bayhorse, South

Digitized by Google

Mountain, Yellow Pine, and Middle Boise districts. Silver ore yielded 51 percent of the State total silver, zinc-lead ore 37 percent, lead ore 8 percent, and gold-silver ore and gold ore 3 percent. The yield of silver from silver ore decreased 2,340,416 ounces, but that from zinc-lead ore increased 404,842 ounces and from lead ore 60,433 ounces.

Eight mines—the Sunshine, Bunker Hill & Sullivan, Mineral Point, Hecla, Polaris, Triumph, Morning, and Page—produced 81 percent of the silver output of the State during 1942. All these mines except the Triumph are in the Coeur d'Alene region.

Copper.—The output of recoverable copper in Idaho in 1942 was 6,860,000 pounds—a 5-percent decrease from 1941. The loss resulted mainly from decreased output of silver-copper ore and copper ore. Silver ore (chiefly from mines in the Coeur d'Alene region) yielded 69 percent of the State total copper, zinc-lead ore 23 percent, copper ore 3 percent, zinc ore 3 percent, and lead ore 2 percent.

The Mineral Point and Sunshine mines produced 64 percent of the total copper output of the State in 1942.

Lead.—The output of recoverable lead in Idaho was 227,818,000 pounds in 1942—an increase of more than 8 percent over 1941. Marked increases in lead output at the Hecla, Page, Sherman, Bunker Hill & Sullivan, Dayrock, and Star properties more than offset large decreases at the Morning and Triumph mines. About 93 percent of the State total lead came from the Coeur d'Alene region; most of the remainder was produced in the Warm Springs, Bayhorse, Port Hill, and Pend d'Oreille districts. Zinc-lead ore and old tailings from the Coeur d'Alene region yielded 81 percent of the State total lead; and lead ore, chiefly from the Coeur d'Alene region, yielded 14 percent. Lead recovered from zinc-lead ore increased 13,185,657 pounds and from lead ore 4,824,358 pounds.

In 1942 the combined lead output of the three largest producers—the Bunker Hill & Sullivan, Hecla, and Morning—was 131,219,137 pounds (127,137,585 pounds in 1941), or more than 57 percent of the State total; other important producers were the Page, Star, Sherman, Tamarack, Triumph, Dayrock, Clayton, and Gold Hunter properties.

Zinc.—The output of recoverable zinc in Idaho was 174,512,000 pounds in 1942—a 10-percent increase over the former record output (1941). The gain was due principally to increased output of zinc from mines in the Coeur d'Alene region, especially from the Hecla, Star, Page, Tamarack, and Spokane-Idaho properties; however, a substantial decrease was reported from the Bunker Hill & Sullivan mine. Nearly 90 percent of the State total zinc in 1942 came from the Coeur d'Alene region and nearly all the remainder from the Warm Springs, South Mountain, Bayhorse, Deadwood Basin, and Alder Creek districts. Zinc-lead ore and old tailings concentrated yielded 97 percent of the State total zinc, and zinc ore concentrated most of the remainder.

Seven mines—the Star, Morning, Hecla, Bunker Hill & Sullivan, Tamarack, Triumph, and Page—produced 82 percent of the State total zinc in 1942.

[1] A floating washing plant supplied with gravel by a dragline excavator is called a "dragline floating dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."
[2] Recovered from 75,362 cubic yards of gravel treated by 5 dry-land dredges.
[3] Recovered from 1,100,575 cubic yards of gravel treated by 7 dragline floating dredges.
[4] Recovered from 7,772,947 cubic yards of gravel treated by 10 floating bucket dredges.

MINING INDUSTRY

The marked increase in output of lead, zinc, antimony, and tungsten, the closing of gold properties in October by Government order, and the serious shortage of labor at mines, mills, and smelters in the Coeur d'Alene region during the summer were the most important features of the mining industry of Idaho during 1942. The production of zinc, antimony, and tungsten was greater than in any year in the history of the State, and the output of lead was the largest since 1930. Zinc-lead ore (by far the chief output of the State) increased 15 percent over 1941 and lead ore nearly 48 percent; gold ore and gold-silver ore combined declined 23 percent, silver ore more than 6 percent, copper ore 72 percent, and zinc ore 9 percent.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Idaho in 1942, with content in terms of recovered metals

Source	Mines producing	Ore	Gold	Silver	Copper	Lead	Zinc
		Short tons	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*	*Pounds*
Dry and siliceous gold ore	88	142,952	35,452	130,336	19,763	99,689	
Dry and siliceous gold-silver ore	7	173,389	7,494	358,263	3,291	60,526	
Dry and siliceous silver ore	18	458,533	331	7,528,893	4,721,804	1,264,769	
	[1] 112	774,874	43,277	8,017,492	4,744,858	1,424,984	
Copper ore	8	2,210	153	27,390	190,653	8,090	
Lead ore	40	313,317	313	1,103,683	153,272	31,978,714	132,762
Lead-copper ore	1	83		12,354	7,262	36,515	
Zinc ore	8	20,561	222	127,670	195,608	261,057	4,355,608
Zinc-lead ore	52	1,789,659	6,475	5,345,830	1,568,347	194,108,640	170,023,630
Total, lode mines	[1] 203	2,900,704	50,440	14,634,419	6,860,000	227,818,000	174,512,000
Total, placers	236		44,580	10,471			
	439	2,900,704	95,020	14,644,890	6,860,000	227,818,000	174,512,000
Total, 1941	855	2,704,680	149,816	16,672,410	7,242,000	209,828,000	158,168,000

[1] A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.

METALLURGIC INDUSTRY

Of the 2,900,704 tons of ore produced in 1942 in Idaho, 2,762,323 tons (95 percent) were treated at concentration plants, 111,772 tons (4 percent) were treated at amalgamation and cyanidation mills, and 26,609 tons (1 percent) were shipped crude to smelters.

Ore treated at concentration plants in 1942 comprised 32,138 tons of gold ore, 168,913 tons of gold-silver ore, 447,130 tons of silver ore, 560 tons of copper ore, 306,083 tons of lead ore, 17,906 tons of zinc ore, and 1,789,593 tons of zinc-lead ore.

Ore treated at straight amalgamation mills in 1942 totaled 11,402 tons, and ore treated at combined amalgamation and concentration plants comprised 97,670 tons. Ore treated at straight cyanidation plants in 1942 totaled 700 tons, and ore treated at combined cyanidation and concentration plants comprised 2,000 tons.

The lead smelter and refinery and the antimony plant of the Bunker Hill & Sullivan Mining & Concentrating Co. at Bradley were operated at capacity in 1942 on ore and concentrates, chiefly from mines and mills in the Coeur d'Alene region. The 100-ton electrolytic zinc plant of the Sullivan Mining Co. near Bradley operated at capacity on concentrates from the same source.

In April 1943, the Bunker Hill & Sullivan Mining & Concentrating Co. completed its zinc-fuming plant at Bradley. According to a report by P. C. Fedderson, smelter superintendent at the Bunker Hill lead smelter, the operation will follow closely that practiced for some years by the Anaconda Copper Mining Co. at East Helena, Mont. The plant will treat all current hot slag and in addition cold reclaimed dump slag; it is expected to handle approximately 400 tons of slag a day, and this will produce about 50 tons of oxide fume containing 30 to 35 tons of zinc and about 5 tons of lead. That portion of the existing slag dump which can be re-treated economically for zinc recovery

Digitized by Google

contains about 1,000,000 tons, with an average zinc content of 10 percent. In September 1942 the Sunshine Mining Co. completed an electrolytic antimony plant (100-ton capacity) adjoining its concentration mill near Kellogg to recover antimony from silver-copper-antimony concentrates.

Mine production of metals in Idaho in 1942, by methods of recovery, in terms of recovered metals

Digitized by Google

Comment on districts with small production has been omitted owing to lack of space.

ADA COUNTY

Snake River district.—Dry-land dredging at three properties in Ada County near Grand View in 1942 recovered 492 fine ounces of gold and 31 fine ounces of silver. Cecil Rhodes operated the Eldridge and Hot Shot groups and John R. Rhodes the Dixie property.

ADAMS COUNTY

Nearly all the output in Adams County in 1942 was copper ore (80 tons) containing gold and silver from the Helena, Lucky Strike, and South Peacock properties near Cuprum in the Seven Devils district.

BLAINE COUNTY

Mineral Hill and Camas district.—The most important mining operation in the Mineral Hill and Camas district in 1942 was by the Lurline Mining Co. at the Camas property, 10 miles west of Hailey; shipments of gold ore during the last 4 months of 1942 totaled 1,460 tons. The remainder of the district output was principally old tailings from the Minnie Moore and Triumph properties and gold ore from the Treasure Vault mine.

Warm Springs district.—Mining of zinc-lead-silver ore from the Triumph-North Star-Independence groups near Ketchum by the Triumph Mining Co. continued to be the most important mining operation in southern Idaho; however, the grade of the ore in 1942 was lower than in 1941. The old 300-ton concentration mill at the North Star mine, which was remodeled in 1941, treated 32,512 tons of low-grade marginal zinc-lead-silver ore in 1942 that could not be mined at a profit in 1941. In addition, 78,148 tons of zinc-lead-silver ore were shipped to custom mills at Bauer and Tooele, Utah. The company was granted a basic quota of about 550 tons of lead and 900 tons of zinc a month. The quota has been revised several times, and as of May 1943 the company was still seeking further revisions. The rest of the district output was mainly gold-silver ore (771 tons) from the Red Cloud mine and gold ore (438 tons) from the June Day mine.

BOISE COUNTY

Boise Basin district (Centerville, Placerville, Idaho City, Pioneerville, Quartzburg).—When the price of gold rose to $35 an ounce in 1935, placer mining, especially bucket dredging, became the most important type of mining in the Boise Basin district; it attained a record output of 22,990 ounces of gold in 1940 but declined to 13,112 ounces in 1942. All bucket dredging ceased in October 1942 owing to the gold-mine closing order of the War Production Board. The Fisher-Baumhoff Co., operating two bucket dredges at Centerville, remained the largest producer of placer gold in the State; the two dredges washed about 1,500,000 cubic yards of gravel and recovered 7,087 fine ounces of gold and 1,788 fine ounces of silver. The Idaho-Canadian Dredging Co. operated its 7½-cubic foot bucket dredge at Idaho City until October 15 and recovered 5,579 fine ounces of gold and 1,368 fine

556250—43——25

Digitized by Google

ounces of silver from 1,394,695 cubic yards of gravel. The rest of the district placer gold was recovered largely by hydraulicking and sluicing at the White Rose, Moe, Fairchild, and Bell Flower properties. The output of lode mines in the district was chiefly high-grade gold-silver ore (269 tons) from the Come-Back mine at Pioneerville. Producers of gold ore included the Coin Bond, Hay Fork, Julian, Mineral Hill, Summit, and Texida properties.

Summit Flat district.—The output of 304 ounces of gold and 135 ounces of silver in the Summit Flat district in 1942 was chiefly lode gold recovered by amalgamation from ore mined at the King, Golden Chariot, San Cristobal, and Viking properties.

BONNER COUNTY

Pend d'Oreille district.—The Whitedelf mine near Clark Fork, the largest producer of silver and lead in the Pend d'Oreille district in 1941, was closed in May 1942 owing to difficulty in obtaining adequate labor and supplies. During the first 4½ months of 1942 about 1,700 tons of silver-lead ore were treated in the company 50-ton flotation plant. The Hope (Elsie K.) mine, also near Clark Fork, was operated throughout 1942 by Hope Silver-Lead Mines, Inc.; 10,320 tons of ore containing 18,500 ounces of silver, 709,350 pounds of lead, and 326,800 pounds of zinc were treated in the company 150-ton flotation plant. In 1942 the company added more flotation equipment to the mill and did considerable metallurgical work in endeavoring to recover the zinc; however, no zinc concentrates were marketed in 1942. Small lots of high-grade silver ore were produced from the Brown Bear mine and lead ore from the Lawrence mine.

BOUNDARY COUNTY

The Idaho-Continental mine in the Port Hill district was operated continuously in 1942 by Trueman Higginbotham; 41,353 tons of ore containing about 45,000 ounces of silver, 2,450,000 pounds of lead, and a little gold and copper were treated in a 90-ton flotation mill.

BUTTE COUNTY

Lava Creek district.—The output of the Lava Creek district in 1942 was 153 tons of zinc ore from the Multa Metals group near Arco and 106 tons of zinc-lead ore from the Hornsilver and Moran mines. All the ore was shipped to a custom milling plant in Utah.

CLEARWATER COUNTY

Virtually all the output in Clearwater County in 1942 was placer gold recovered from stream gravel at various claims in the Burnt Creek, Independence Creek, and Pierce districts. The chief operation consisted of dredging gravel at the Meadow claim on French Creek in the Pierce district.

CUSTER COUNTY

Alder Creek district.—Lessees operated the White Knob property, 4 miles south of Mackay, in 1942 and shipped 2,109 tons of crude zinc ore to the International slag-fuming plant at Tooele, Utah, and 46 tons of silver-lead ore to a smelter; shipments of zinc ore to the slag-fuming plant ceased in July. The rest of the district output was crude

Digitized by Google

copper ore (1,274 tons) shipped from the Empire mine at Mackay. This mine was closed in August, but in December the Federal Bureau of Mines started a drilling project.

Bayhorse district.—The mining of zinc-lead ore at the Clayton mine by Clayton Silver Mines in 1942 was the most important operation in the Bayhorse district. In May the company completed installation of additional milling equipment for recovering zinc, and during the last 7 months of the year lead concentrates and zinc concentrates were shipped to smelters; only lead concentrates were produced during the first 5 months. The mill treated 38,014 tons of ore containing 146,443 ounces of silver, 3,120,000 pounds of lead, 3,193,000 pounds of zinc, and a little gold and copper. The remainder of the district output was largely lead-silver ore (225 tons) and copper-silver ore (208 tons) from the Ramshorn mine and lead ore (624 tons) from the South Butte mine.

Stanley and Stanley Basin district.—The Valley Creek property near Stanley was operated a few months in 1942 by the Western Gold Exploration Co.; about 2,000 tons of gold ore were concentrated, and nearly all the concentrates were cyanided.

Yankee Fork district.—Placer gold recovered by bucket dredging was the principal output of the Yankee Fork district in 1942. The 8-cubic foot bucket dredge of the Snake River Mining Co. at Sunbeam washed 1,428,326 cubic yards of gravel, which yielded 4,787 fine ounces of gold and 2,412 fine ounces of silver; operations ceased in October owing to Government regulations. The lode output of the district was chiefly gold-silver ore (3,224 tons), treated by amalgamation and concentration, from the General Custer-Lucky Boy group; this property was shut down May 1. About 20 tons of high-grade gold ore (some lots averaging 9 ounces of gold to the ton) were produced from the Fourth of July claim. Other gold producers included the Bachelor Mountain, Last Chance, and Yankee Fork properties.

ELMORE COUNTY

Middle Boise (Atlanta) district.—In 1942, as in 1941, the Middle Boise district was the largest gold-producing area in the State, resulting chiefly from operation of lode property (Boise-Rochester-Monarch groups) by Talache Mines, Inc. The company treated 87,747 tons of gold ore in its 400-ton amalgamation and concentration mill compared with 121,355 tons in 1941. In addition to gold and silver, the ore contains arsenic and tungsten; in 1942 some tungsten concentrates were produced and marketed. The rest of the district output was principally placer gold, recovered chiefly by the 7½-cubic foot bucket dredge of Boise King Placers. The dredge treated 1,310,879 cubic yards of stream gravel in 1942 and recovered 6,346 fine ounces of gold and 2,149 fine ounces of silver; operations ceased October 30.

GEM COUNTY

West View district.—In 1942 gold ore (6,650 tons) from the Lincoln group at Pearl was the most important output in the West View district. The mine and 75-ton flotation mill were operated until December 15, when operations ceased, probably for the duration of the war. The remainder of the district output was largely zinc-lead ore (141 tons) from the Friday mine.

Digitized by Google

IDAHO COUNTY

Burgdorf-Marshall Lake district.—The Golden Anchor Mining Co. operated its mine and 50-ton amalgamation-concentration plant at Czizek until April 30, 1942, when operations were closed permanently; 2,827 tons of gold ore were treated in 1942 and yielded 1,498 ounces of gold and 4,482 ounces of silver. The mine had been a large producer of gold since 1935. Gold ore was produced also from the Gold Crest, Jewell, and Leadville properties. The district output of placer gold and silver was recovered by hydraulicking and sluicing at the Ruby and Black Creek claims.

Dixie district.—A dragline floating dredge operated a few months in 1942 at the Dixie Placers and recovered 196 fine ounces of gold and 36 fine ounces of silver. The rest of the district output was principally lode gold from the Slip Easy and Ontario properties.

Elk City district.—Four dredges (three dragline and one bucket-line) in the Elk City district treated 919,880 cubic yards of gravel in 1942 and recovered 5,805 fine ounces of gold and 1,083 fine ounces of silver. The bucket-line dredge (on Crooked River), operated by H. & H. Mines, was again the largest producer; it operated from January 1 to June 20 and recovered 2,859 fine ounces of gold and 560 fine ounces of silver. The dragline dredges, operated by the American River Mining Co. and the Tyee Mining Co., were also large producers of gold. Nearly all the lode output of the district was gold ore cyanided (220 tons) from the Blue Ribbon mine.

Newsome district.—Gold Hill Placers operated its dragline floating dredge on Newsome Creek 3 months in 1942 and recovered 500 fine ounces of gold and 105 fine ounces of silver from 82,000 cubic yards of gravel. A little placer gold and silver was produced from the Hay Fork claim.

Orogrande district.—The principal output in the Orogrande district in 1942 was placer gold recovered from a property on Crooked River by the 2-cubic foot bucket dredge of the Mt. Vernon Co.; the dredge treated 167,966 cubic yards of gravel from March 15 to August 8 and recovered 955 fine ounces of gold and 204 fine ounces of silver. The lode output of the district was largely old mill cleanings from the Penman and Orogrande-Frisco mills.

Ramey Ridge district.—The Snowshoe mine near Big Creek was the only producer in the Ramey Ridge district in 1942; about 3,000 tons of gold ore were treated in a 25-ton amalgamation and concentration mill.

Ten Mile district (Golden).—All the output in the Ten Mile district in 1942 was gold ore, chiefly from the Center Star mine. Lessees operated the mine and treated about 4,900 tons of gold ore in a 50-ton gravity-flotation mill; the jig concentrates were treated by amalgamation, and the flotation concentrates were shipped to a smelter. Other producers of gold ore included the Blackbird, Bob, Lone Pine, and Shamrock properties.

Warren district.—The principal output in the Warren district in 1942 was placer gold recovered by the 2½-cubic foot bucket-line dredge operated on Warren Meadows by W. W. Prather; the dredge treated about 215,000 cubic yards of gravel and recovered 1,090 fine ounces of gold and 358 fine ounces of silver. Other placer producers included the Cook, Smith Gulch, and Steamboat properties. Nearly all the output from lode mines in the district was gold ore (amalgamated) from the Rescue mine.

Digitized by Google

LATAH COUNTY

Hoodoo district.—In 1942, as in 1941, the output of the Hoodoo district was placer gold and silver, virtually all recovered by the 4½-cubic foot bucket-line dredge of Northwest Goldfields. The dredge operated from January 1 to October 14 and treated 1,021,726 cubic yards of gravel.

LEMHI COUNTY

Blue Wing district.—The Ima mine at Patterson, only producer in the Blue Wing district, was operated continuously in 1942 by the Ima Mines Corporation; 25,340 tons of ore containing 45,612 ounces of silver, 75,000 pounds of copper, 126,000 pounds of lead, 506,000 pounds of iron, and 253,000 pounds of tungsten were treated in a 150-ton gravity and flotation mill equipped with a magnetic separator. Iron concentrates (640 tons) containing chiefly silver, copper, and lead were shipped to a smelter in Utah, and tungsten concentrates (113 tons) were shipped to an eastern market.

Eureka district.—Lessees operated the Pope-Shenon mine a few months in 1942 and treated 560 tons of copper ore in a concentration mill. Gold ore (480 tons) from the Queen of the Hills mine was amalgamated. The rest of the district output was placer gold recovered from the Best Bet and Queen Gulch properties.

Gibbonsville district.—The principal output in the Gibbonsville district in 1942 was placer gold recovered chiefly by two dredges. A dragline floating dredge (Smith Bros.) at the Hagel property recovered 2,466 fine ounces of gold and 203 fine ounces of silver from 415,000 cubic yards of gravel, and a 4-cubic foot bucket-line dredge (Idaho-Warren Dredging Co.) at the Hughes Creek Placer recovered 1,900 fine ounces of gold and 123 fine ounces of silver from 380,000 cubic yards of gravel. The lode output of the district was gold ore from the Nevada and Red Star mines.

Mineral Hill district.—Gold Producers, Inc., continued in 1942 to operate the Grunter open-pit mine at Shoup and treated about 20,000 tons of gold ore by flotation. A little high-grade gold ore (15 tons) from the Rico claim was shipped direct to a smelter.

Nicholia district.—Lessees operated the Viola mine near Reno and shipped 434 tons of carbonate zinc ore to the International slag-fuming plant at Tooele, Utah.

Texas district.—The principal output in the Texas district in 1942 was 820 tons of crude silver-lead ore from the Latest Out mine near Gilmore.

OWYHEE COUNTY

Carson district (*Silver City, De Lamar*).—The De Lamar Milling Corporation operated its 250-ton flotation mill continuously in 1942 until December 22, when the plant was closed permanently; 72,052 tons from De Lamar waste dumps were treated, and the resulting high-grade gold-silver concentrates (274 tons) were shipped to a smelter in Utah. The rest of the district output was largely gold ore from the Pauper and South Central properties.

South Mountain district.—Mining operations by the South Mountain Mining Co. at the Golconda mine were continuous throughout 1942. The company shipped 11,188 tons of ore containing 260 ounces of gold, 132,243 ounces of silver, 225,718 pounds of copper, 139,610 pounds of lead, and 3,870,161 pounds of zinc to the International flotation mill at Tooele, Utah.

SHOSHONE COUNTY

COEUR D'ALENE REGION

The value of the metal output of the Coeur d'Alene region was $38,880,253 in 1942, a 20-percent gain over 1941. The output of lead increased 11 percent, zinc 15 percent, and copper less than 1 percent; gold decreased 21 percent and silver nearly 12 percent. The output of zinc in 1942 exceeded the former record of 1941, and the output of lead was the largest since 1930.

Calculated from reports of production for the first quarter of 1943 and of new producers of zinc, the output of zinc in 1943 should be about 4 percent greater than in 1942; however, the output of lead will be less.

The chief producers of zinc in the region in 1942, according to rank (each producing more than 11,000,000 pounds), were the Star, Morning, Hecla, Bunker Hill & Sullivan, Tamarack, and Page properties; the chief producers of lead, according to rank (each producing more than 10,000,000 pounds), were the Bunker Hill & Sullivan, Hecla, Morning, Page, Star, Sherman, and Tamarack properties. Nearly 71 percent of the material produced in the Coeur d'Alene region in 1942 was zinc-lead ore and old tailings, more than 18 percent silver ore, and 10 percent lead ore. Nearly all mines worked 6 days a week and milling plants 7 days a week. Miners' wages increased from $6.25 a shift in March 1941 to $8.25 a shift in May 1942, the highest ever paid in the district. In 1942 the region was the largest silver-producing area in the United States; it ranked second in lead and third in zinc.

Mine production of gold, silver, copper, lead, and zinc in the Coeur d'Alene region, Shoshone County, 1941–42, and total, 1884–1942, in terms of recovered metals

Year	Mines producing		Ore	Gold (lode and placer)	Silver (lode and placer)	Copper	Lead	Zinc	Total value
	Lode	Placer							
			Short tons	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*	*Pounds*	
1941	58	21	2,051,390	3,419	14,678,356	5,957,000	191,057,000	136,642,000	$32,398,932
1942	49	7	2,327,417	2,688	12,977,287	5,986,000	212,947,000	156,625,000	38,880,253
Total, 1884–1942	------	------	(1)	385,085	400,543,895	[2] 60,260	[2] 5,245,463	[2] 886,546	978,091,576

[1] Figures not available.
[2] Short tons.

Beaver district.—All the lode output (83,513 tons of ore) in the Beaver district in 1942 was zinc-lead ore; the chief producers were the Interstate-Callahan mine and waste dump, the Sunset mine, and the Amazon-Manhattan group. The Daylight Lease operated the Interstate-Callahan mine throughout the year and hauled 26,029 tons of ore containing principally silver, lead, and zinc to Zanetti Bros. flotation mill near Wallace; 17,453 tons of similar ore from the mine waste dump, operated by Zanetti Bros., were treated in the same mill. About 20,200 tons of zinc-lead ore from the Sunset mine were treated in the Golconda 250-ton custom flotation mill near Wallace. Zinc-lead ore (11,115 tons) from the Amazon-Manhattan group was treated in the Dayrock and Hercules custom mills, also near Wallace. Other producers of zinc-lead ore were the Silver Tip (Portland), Port Arthur, Monarch, and Sitting Bull properties.

Digitized by Google

Evolution district.—The principal output in the Evolution district in 1942 was silver ore (414,019 tons) from the Sunshine, Mineral Point, and Polaris properties near Osburn. The chief producer was the Sunshine mine, although its output of silver ore decreased from 305,180 tons in 1941 to 251,700 tons in 1942 and the production of silver from 7,138,426 to 4,976,859 ounces. According to the printed annual report of the Sunshine Mining Co., the decrease in tonnage of ore mined was due to a labor shortage. A constructive step was taken by the Army to relieve the shortage by releasing soldiers with previous coal- and metal-mine experience for employment in nonferrous metal mines. Late in the fall 109 furloughed soldiers were employed at the Sunshine mine, and more could be used. Indications point to a further shortage of labor during the spring of 1943, and production depends more on manpower than any other factor. In March 1942 the company started to construct a plant to recover, by leaching and electrolytic deposition, the antimony contained in the high-grade silver-copper-antimony concentrate. A pilot antimony plant operated through May, when it was shut down for the transfer and installation of its equipment at the new full-sized plant. During the 5 months operated, the pilot plant produced 142,400 pounds of antimony metal. The new plant began operating the middle of September and has processed the total tonnage of silver-copper-antimony concentrate produced since September 1; to the end of the year it had produced 250,000 pounds of antimony metal. The residue remaining after the antimony had been leached was shipped to a copper smelter for the recovery of the silver and copper content. In 1942 the 1,200-ton differential flotation plant produced 3,121 tons of high-grade silver-copper-antimony concentrates and 4,329 tons of low-grade silver-iron concentrates. The ore reserves are estimated at 583,000 tons—a decrease of 167,000 tons from the estimate of 1941. The 600-ton flotation mill at the Mineral Point mine of the Coeur d'Alene Mines Corporation treated 122,301 tons of silver-copper-antimony ore in 1942. The company reported that ore was mined on all levels from the 600- to the 1,800-foot, inclusive. A raise driven from the 600-foot level shows a good grade of ore for 300 feet above the level. Drifting west on the 1,600- and 1,800-foot levels shows a lengthening ore shoot to the west, and a major portion of ore output is now coming from the two levels. The concentrates (4,914 tons) contained 1,586,460 ounces of silver, 3,132,398 pounds of copper, and 1,839,936 pounds of antimony. The property was the largest producer of copper in Idaho and ranked second in antimony and third in silver. About 40,000 tons of silver ore from the Polaris mine were treated in the company 200-ton flotation mill; the concentrates contained 63 ounces of gold, 773,074 ounces of silver, 238,450 pounds of copper, 135,800 pounds of lead, 194,524 pounds of antimony, and some iron. The company reported that development in 1942 aggregated 1,977 feet, of which 879 feet were in ore and 1,098 feet in waste; ore reserves are estimated at 29,150 tons. The rest of the district output was virtually all old zinc-lead tailings (3,789 tons) from two dumps at Osburn.

Hunter district (Mullan).—In 1942, as in 1941, the output of recoverable zinc (68,124,300 pounds) in the Hunter district was larger than in any other district in Idaho; the chief producer was the Star mine of the Sullivan Mining Co. at Burke. The 1,000-ton flotation

Digitized by Google

mill at the mine treated 242,900 tons of ore yielding lead concentrates and zinc concentrates, which contained 240,069 ounces of silver, 16,678,000 pounds of lead, and 42,269,434 pounds of zinc; the mine was again the largest producer of zinc in Idaho. The company reported that the mine operated at capacity to June 1, when a shortage of labor began in the district; by September operations dropped to 50 percent of capacity. The output of zinc-lead-silver ore from the Morning mine of the Federal Mining & Smelting Co. at Mullan decreased to 236,902 tons in 1942 from 270,787 tons in 1941. The 1,250-ton flotation mill at the mine operated continuously in 1942 and yielded lead concentrates and zinc concentrates containing 200 ounces of gold, 622,530 ounces of silver, 32,405,528 pounds of lead, and 36,156,146 pounds of zinc. The mine ranked second in the State in zinc output and third in lead. According to the printed annual report of the company, the labor shortage became so acute during the summer that underground work at the mine was placed on a one-shift-a-day basis August 17. This continued until November 9, when some improvement in the labor supply permitted resumption on a two-shift-a-day basis; ore production during the summer was only about 50 percent of normal. In the last 6 months of 1942 operations at the mine resulted in earnings of only $54,911 owing to increased operating expense and shortage of labor. In 3 of these months there was an actual operating loss. Were it not for the fact that the quota was reduced, it is doubtful if the Morning operations could be conducted at much profit and might result in an actual loss. Leasing operations at the Gold Hunter mine produced 65,417 tons of silver-lead ore in 1942, which was treated in the 500-ton Gold Hunter flotation plant. The rest of the district output comprised 6,756 tons of zinc-lead ore from the Golconda mine and 5,250 tons of similar ore from the Lucky Friday mine, all treated in the 250-ton custom flotation mill of Golconda Lead Mines near Wallace.

Lelande district (Burke, Mace, Frisco).—Zinc-lead-silver ore from the Hecla mine at Burke was, as usual, the most important output in the Lelande district in 1942. The company reported that 274,938 tons of zinc-lead-silver ore were treated in the 900-ton flotation plant at the mine, and 5,474 tons of crude silver-lead ore were smelted. The concentrates and crude ore contained 340 ounces of gold, 1,106,460 ounces of silver, 378,764 pounds of copper, 43,190,323 pounds of lead, and 25,570,047 pounds of zinc; the mine ranked second in the State in lead output, third in zinc, and fourth in silver. According to the printed annual report of the company, capacity operations at the Hecla mine were maintained for the first 8 months of the year, after which production was cut 15 percent. Development in 1942 totaled 3,576 feet, of which 2,316 feet were in ore and 1,260 feet in waste; no additional ore of importance was discovered. Ore reserves at the end of 1942 are estimated at 145,522 tons. Development and an increase in width in some stopes resulted in gaining some tonnage over the estimate for 1941. This, together with the decreased output per month, has extended the life of mine operations. Beginning about May 1, 1943, the declining tonnage from the mine will be supplemented in the mill with ore from the Silver Cable lease in Montana, and with old tailings deposited at Osburn, Idaho, estimated to contain 2,000,000 tons of material averaging about 34 pounds of lead and about 40 pounds of zinc to the ton. The company has

Digitized by Google

built a sink-and-float plant on the property to handle 2,000 tons of material a day; this plant will reject approximately 40 percent as waste, and the remaining product will be treated at the Hecla and Polaris mills. It is expected that milling will begin about May 1, 1943.

The Sherman Lead Co. operated its mine and 300-ton flotation mill throughout the year. The company reported that 69,804 tons of ore were treated, containing 434,962 ounces of silver, 13,938,580 pounds of lead, and 3,000,000 pounds of zinc. Heretofore, no zinc has been recovered, but in November the mill started producing some zinc-lead concentrate in addition to lead concentrate. Leasing operations (Hull Lease) at the Frisco mine produced 27,067 tons of zinc-lead milling ore in 1942. In March 1942 the Federal Mining & Smelting Co., owners of the mine, began unwatering the lower levels, which have been flooded since 1916. Production by the company started November 1, and during the last 2 months of the year 2,770 tons of zinc-lead ore were treated in the Morning mill. The company reported that from the present outlook it is believed the mine will produce a substantial tonnage of zinc-lead ore in 1943. The remainder of the district output was largely old zinc-lead tailings (27,673 tons) deposited at various places along Canyon Creek above Wallace; 23,961 tons of tailings were hauled by the Small Leasing Co. to the Golconda custom mill.

Placer Center district.—The chief output in the Placer Center district in 1942 was zinc-lead ore from the Tamarack mine, treated in the company 300-ton flotation mill. According to the printed annual report of the Tamarack & Custer Consolidated Mining Co., the mine produced 110,735 tons of ore in 1942 containing 203,522 ounces of silver, 11,897,235 pounds of lead, and 17,693,087 pounds of zinc. Despite the large production of ore in 1942 and the unfavorable results of development on the 2,000-foot level, the ore reserves were not seriously diminished at the end of the year. The average crew required at the Tamarack mine to maintain normal production and development is not less than 160 men. Only during the first 4 months and the last 2 months of 1942 was enough manpower available. Although production did not suffer greatly, development had to be decreased. The mine and mill are prepared for maximum production in 1943. The Dayrock Mining Co. operated its mine and 200-ton flotation mill continuously in 1942 and treated 26,278 tons of silver-lead ore. According to the printed annual report of the company the ore contained 188,241 ounces of silver, 4,772,720 pounds of lead, and 750,000 pounds of zinc; however, no zinc was recovered. Ore reserves were substantially diminished in 1942, as new discoveries of ore were equivalent to only a fraction of the tonnage extracted during the year. The 500-foot level was extended westerly 578 feet but there is difficulty in tracing the Dayrock vein downward. The remainder of the district output was mainly old zinc-lead tailings (2,823 tons) from a property near Wallace and zinc ore (2,200 tons) from the Success mine operated by lessees.

Yreka district (*Kellogg*).—The value ($11,050,955) of the metal output of the Yreka district and the output of recoverable lead (84,693,300 pounds) in 1942 were larger than in any district of Idaho, and that of recoverable zinc and silver ranked second. Zinc-lead-silver ore from the Bunker Hill & Sullivan mine at Kellogg was, as usual, the principal output in the district; 408,549 tons of ore were

Digitized by Google

treated by gravity and flotation concentration and 68,833 tons of old tailings (silver-lead-iron) were treated by straight gravity concentration. The company reported that the lead concentrates and zinc concentrates produced from both ore and old tailings contained 1,657,425 ounces of silver, 60,087,300 pounds of lead, and 27,223,700 pounds of zinc. The property remained the largest producer of lead and second in output of silver in Idaho and was fourth in zinc. According to the printed annual report of the company, exploration in 1942 resulted in finding good ore in quantity at several points. The Emery vein, extensively mined on 21 level, has been cut 400 feet lower on the 23 (bottom) level of the mine and shows very well, both as to grade and quantity, with good promise for further deeper mine development. An important find of ore on 13 level was made in an area of the mine not heretofore prospected. Westward mining on 21 level continues to disclose ore of importance. Ore reserves on January 1, 1943, undercut and available for mining, totaled 2,839,620 tons of zinc-lead-silver ore—an increase of 109,222 tons over the ore reserves reported January 1, 1942.

The Blackhawk and Page mines and the Page 500-ton flotation mill were operated continuously in 1942 by the Federal Mining & Smelting Co. The company reported that 139,848 tons of zinc-lead ore from the Page mine and 14,992 tons of similar ore from the Blackhawk mine contained 602,319 ounces of silver, 24,526,600 pounds of lead, and 16,598,850 pounds of zinc. According to the printed annual report of the company "the labor shortage experienced by most of the companies in the Coeur d'Alene region did not affect seriously operations at these properties." Development on the 2,100 and 2,400 levels discovered ore shoots of excellent length and good average grade.

The 100-ton flotation mill at the Constitution mine (Spokane-Idaho Mining Co.) on Pine Creek operated throughout the year and treated 20,307 tons of zinc-lead ore. Milling of zinc-lead ore from the Highland-Surprise mine was begun in June and suspended in November; during the 5 months a total of 14,474 tons of zinc-lead ore was treated. The Little Pittsburg mine and its 100-ton flotation mill on Pine Creek were operated in 1942 by the Denver Development Co.; 11,656 tons of ore were treated, containing an average of 1.50 ounces of silver to the ton, 3.31 percent lead, and 8.32 percent zinc. The remainder of the district output was mainly 9,793 tons of old tailings (silver-lead) from the Sierra Nevada property, 7,983 tons of silver ore from the Crescent mine, 7,500 tons of zinc-lead ore from the Douglas mine dump, 3,700 tons of old zinc-lead tailings from various dumps, and zinc-lead ore from the Sidney and Liberal King mines.

VALLEY COUNTY

Deadwood Basin district.—The Hall-Interstate group, 54 miles east of Cascade, was operated in 1942 by the Callahan Zinc-Lead Co.; 7,733 tons of zinc-lead ore were treated by flotation, yielding 240 tons of silver-lead-copper concentrates and 590 tons of zinc concentrates.

Thunder Mountain district.—The output of the Thunder Mountain district in 1942 was 943 fine ounces of gold and 609 fine ounces of silver recovered from gold ore amalgamated from the Sunnyside-Dewey group and 44 fine ounces of gold and 31 fine ounces of silver recovered principally from the Bonanza placer on Mule Creek.

Digitized by Google

Yellow Pine district.—The practice of treating gold-silver-antimony-tungsten ore from the Yellow Pine mine was changed in 1942 from bulk sulfide flotation to selective flotation of antimony minerals from pyrite and arsenopyrite, and tabling of flotation-made tungsten concentrate was abandoned for improved flotation metallurgy. There were 96,861 tons of ore treated in 1942, containing an average of 0.039 ounce of gold and 1.41 ounces of silver to the ton, 4.79 percent antimony, and 2.59 percent tungsten. The 400-ton mill yielded 2,294 tons of high-grade tungsten concentrate, 6,887 tons of low-grade tungsten concentrate, 7,564 tons of gold-silver-antimony concentrate, and 816 tons of gold-antimony-iron concentrate. The capacity of the mill was increased to 800 tons of ore a day early in 1943.

Butte or Summit Valley district	412

SUMMARY

Copper remained the chief source of metal value in Montana and was the only metal to show increased output in 1942. The aggregate value of the gold, silver, copper, lead, and zinc produced from Montana ores and gravels was, in terms of recoverable metal, $60,129,853 compared with $59,181,627 in 1941 (see fig. 1). This slight advance was due to a greater output of copper and a higher average price paid for copper, lead, and zinc in 1942. Gold and silver production—more particularly gold—was cut drastically by the widespread closing of gold mines in every section of Montana. The output of lead and zinc was affected seriously when all zinc-lead mines at Butte, operated by the Anaconda Copper Mining Co., closed in late May; however, this closing enabled the Anaconda Copper Mining Co. to maintain and even increase its output of copper. Silver Bow County, which includes the Butte area and yields nearly all the copper and most of the zinc and silver output of the State, produced gold, silver, copper, lead, and zinc valued at $46,942,464 in 1942 compared with $44,195,725 in 1941. This increase was due to the greater output of copper by the Anaconda Copper Mining Co.

Several factors influenced the production of metals in Montana during 1942. The great majority of the mining districts in Montana are primarily gold-producing; in consequence of, first, a serious labor shortage and, finally, the Government closing order issued in October, many of the large gold mines either shut down or greatly reduced their output. This labor shortage was first felt in several of the districts in late 1941 or early in 1942 and prompted many gold producers, more particularly operators of lode mines, to make and carry out plans for suspending operations for the duration of the war even before the Government issued its closing order in October. Gold production from Beaverhead, Broadwater, Madison, Park, Lewis and Clark, Jefferson, Phillips, and Powell Counties was affected most.

A premium pay plan stimulated the production of copper, lead, and zinc. The plan, authorized by the Metals Reserve Company (a Government agency), effective February 1, 1942, granted producers of base

Digitized by Google

metals a premium of 5 cents a pound for copper and 2¾ cents a pound for lead and zinc produced in excess of certain fixed basic quotas. This plan was modified further to include one additional premium of 2¾ cents for lead and two additional premiums of 2¾ cents for zinc. The effective date of the modification was the opening of business December 1, 1942. Eligibility for these additional premiums was based upon the producer's ability to maintain the present rate of production or to increase output, chiefly from marginal ore bodies. Each case was to be considered independently by the quota committee at Washington, D. C.

Although the Government stimulated the production of base metals by means of premium payments and successive reductions of quotas for various mining companies, the effect of the program was more than offset by the critical shortage of labor at mines, mills, and smelters. Several plans were tried to alleviate this shortage, including wage increases, taking miners from gold mines, stabilization of labor at mines, and the furloughing of soldier-miners to work in the mines. The last plan was the most helpful action taken, although it, too, failed to satisfy the full need. During October and November over 4,000 soldiers were furloughed for service in western mines. Of this number, Montana received about 1,100 men, most of whom were employed at the copper mines at Butte. As these mines, operated by the Anaconda Copper Mining Co., had previously taken over miners from the closed zinc mines, the addition of the soldiers tended to raise the number employed at the copper mines to an operating minimum. The company still needed approximately 700 trained miners before the zinc mines could be reopened.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1938–42

Year	Gold [1]	Silver [2]	Copper [3]	Lead [4]	Zinc [4]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1938	$35.00	[5] $0.646+	$0.098	$0.046	$0.048
1939	35.00	[6] .678+	.104	.047	.052
1940	35.00	[7] .711+	.113	.050	.063
1941	35.00	[7] .711+	.118	.057	.075
1942	35.00	[7] .711+	.121	.067	.093

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.

[2] Treasury buying price for newly mined silver.

[3] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Company for over-quota production but excludes value of foreign copper delivered to Metals Reserve Company for domestic consumption.

[4] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Company for over-quota production.

[5] $0.64646464. [6] $0.67878787. [7] $0.71111111.

[1] Floating washing plant supplied with gravel by a dragline excavator is called a "dragline dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."
[2] Figures for sluicing and hydraulic include those for drift mining.

Gold.—Montana ores and gravels yielded 146,892 fine ounces of gold in 1942 compared with 246,475 ounces in 1941—a 40-percent decrease; the output from lode mines decreased 79,214 ounces and from placer mines 20,369 ounces. Siliceous ores yielded 55 percent of the State total gold, and base-metal ores 17 percent; there was a decrease from all classes except copper ore. Losses in gold output were general throughout the State but were largest in Madison, Broadwater, Lewis and Clark, Silver Bow, Phillips, Park, and Beaverhead Counties; slight increases were noted in Flathead and Judith Basin Counties, but these counties have negligible importance as gold producers. Gold ore mined totaled 322,140 tons, compared with 695,481 tons in 1941, and included 251,939 tons treated in amalgamation and cyanidation mills, 30,873 tons in concentrating mills, and 39,328 tons shipped crude to smelters. Ore treated at amalgamation and cyanidation plants (with or without concentrating equipment)

Digitized by Google

yielded 25 percent of the State total gold, that at concentrating mills 22 percent, ores of all classes shipped crude to smelters 25 percent, and placers 28 percent.

The leading gold producers in Montana in 1942 (not representative of capacity to produce, but merely of good fortune in keeping adequate operating personnel) were the company-operated copper mines of the Anaconda Copper Mining Co. at Butte, the West Mayflower property in Madison County, the Winston dredge operating on Prickly Pear Creek near Clancey, the Ohio Keating mine in Broadwater County,

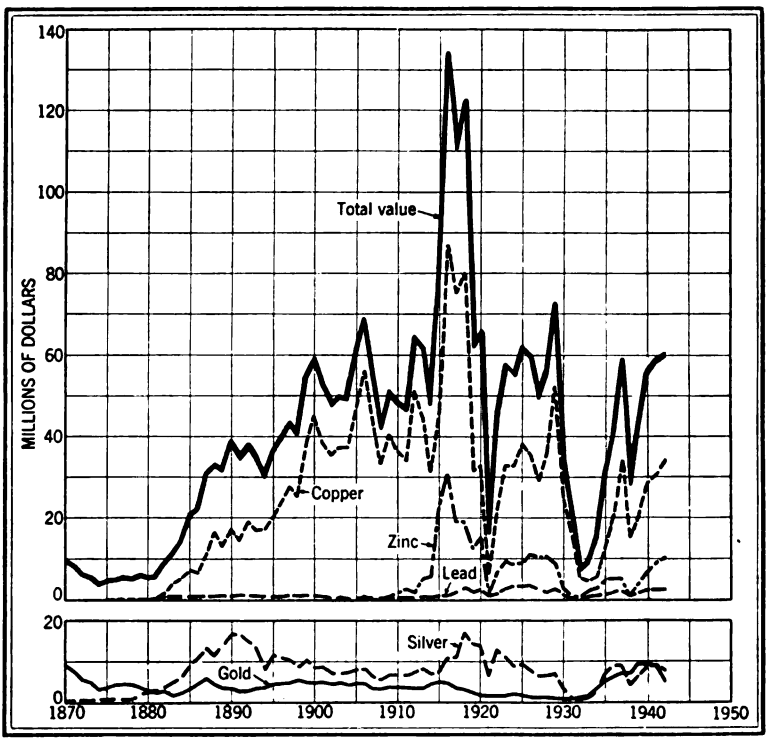

FIGURE 1.—Value of mine production of gold, silver, copper, lead, and zinc, and total value in Montana, 1870-1942.

Porter Bros. dredge near Helena, and the Perry Schroeder dredge on Missouri River in Lewis and Clark County.

Silver.—The output of recoverable silver in Montana in 1942 was 11,188,118 fine ounces compared with 12,386,925 ounces in 1941—a 10-percent decrease. This loss in output can be attributed almost entirely to the closing of all zinc mines of the Anaconda Copper Mining Co. in late May 1942, as these mines produced over 1,000,000 ounces of recoverable silver during nearly 6 months of operation. Copper ore yielded 56 percent of the State total silver, zinc-lead ore 22 percent, siliceous ore 20 percent, and lead ore, zinc ore, and placers together 2 percent. Ore treated at concentration mills yielded 83 percent of the total silver, and crude smelting ore 16 percent. The output of silver ore was 134,153 tons and of gold-silver ore 77,231 tons.

Copper mines, dumps, tailings piles (at Anaconda), zinc mines at

Digitized by Google

Butte, and the Flathead mine in Flathead County, all operated by the Anaconda Copper Mining Co., produced 75 percent of the State total silver. Other large producers included the Granite-Bimetallic mine (tailings) in Granite County; the Lexington group in the Montana district, Cascade County; the Emma mine at Butte (including by-product silver); and the St. Joseph Lead Co. property in Judith Basin County.

Copper.—Copper produced in Montana in 1942, in terms of recoverable metal, was 282,388,000 pounds, compared with 256,072,000 in 1941—a 10-percent gain. This gain was due entirely to the greater output of the Anaconda Copper Mining Co., which again was the only important copper producer in Montana. All active copper mines at Butte are owned and operated by the Anaconda Copper Mining Co., except the property of the North Butte Mining Co. In 1942 this property was operated by the Anaconda Copper Mining Co. through contract agreement. Copper produced from all sources at Butte gained in 1942, except that derived from the treatment of mine dumps; the quantity from this source is comparatively small, and the loss was easily offset by gains elsewhere. Copper ore and precipitates yielded gold, silver, and copper valued at $38,408,147, or 64 percent of total State value.

Lead and zinc.—The value of the production of lead and zinc in Montana, in terms of recoverable metals, increased in 1942 compared with 1941; however, the increases in total value were due to higher average price for the metals, as the quantities decreased. Zinc showed a 12-percent gain in value but a 10-percent decrease in quantity. Lead showed an 11-percent gain in value but a 6-percent loss in quantity. The closing, on May 25, of all zinc mines at Butte operated by the Anaconda Copper Mining Co. was the chief cause of decreased output of both metals. This closing is calculated to have reduced the output of lead from Montana about 7,000,000 pounds and the output of zinc about 40,000,000 pounds. The output from the slag-fuming plant at East Helena operated by the Anaconda Copper Mining Co. increased in 1942 by 811,000 pounds in lead and 2,878,000 pounds in zinc. The Emma mine, operated by the Anaconda Copper Mining Co. under lease, reported a decrease of about 1,000,000 pounds in lead and 5,000,000 pounds in zinc from zinc-lead ore but a gain of about 3,600,000 pounds in lead and about 8,200,000 pounds in zinc as a byproduct.

In 1942 the leading sources of zinc, named in order of output, were the slag-fuming plant at East Helena, all zinc mines operated by the Anaconda Copper Mining Co. at Butte, the Emma byproduct zinc, the Poulin mine at Butte, the Mike Horse mine in Lewis and Clark County, the Emma mine at Butte, the St. Joseph Lead Co. property in Judith Basin County, and the Hecla slag dump in Beaverhead County; these sources supplied 96 percent of the State total. The leading lead producers in Montana in 1942 were all zinc mines at Butte, the Emma byproduct lead, the Mike Horse mine in Lewis and Clark County, the Jack Waite mine in Sanders County, the slag-fuming plant at East Helena, the St. Joseph Lead Co. property in Judith Basin County, the Flathead property in Flathead County, the Forest Rose properties in Granite County, and the Mount Washington mine in Jefferson County; these sources contributed 80 percent of the State total.

[1] A floating washing plant supplied with gravel by a dragline excavator is called a "dragline dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."

MINING INDUSTRY

Continuous operation of the copper mines at Butte by the Anaconda Copper Mining Co., at the expense of closing the zinc mines, caused the State output of copper to increase; and the closing of the zinc mines at Butte caused the production of silver, lead, and zinc to decrease. However, despite this decrease the output of zinc and zinc-lead ore increased in several counties, principally Judith Basin, Lewis and Clark, Beaverhead, and Granite. The widespread closing of gold mines, both lode and placer, resulted in a sharp drop in gold output. Metals from ores treated at amalgamation and cyanidation plants and ore shipped crude to smelters declined in 1942.

Decreases of 20,369 fine ounces in gold and 3,098 fine ounces in silver were noted in the yield from placer mines. Seven connected-bucket floating dredges were active in 1942. They treated 7,539,916 cubic yards of gravel and recovered gold valued at $1,094,905 indicating an average recoverable gold value of 14.5 cents per cubic yard treated. Dragline and power shovels with both dry-land and floating washing plants were reported in operation at 14 properties. The plants washed 976,651 cubic yards of gravel and recovered gold valued at $252,945, indicating an average recoverable gold value of 25.9 cents to the cubic yard washed.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

[1] Includes 5,327,407 pounds recovered from precipitates.
[2] Includes 204,362 tons of current slag fumed.
[3] A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.
[4] Includes 5,503,585 pounds recovered from precipitates.

METALLURGIC INDUSTRY

The 5,678,280 tons of ore produced from Montana lode mines in 1942 were treated as follows: 12,773 tons at amalgamation plants, 239,166 tons at cyanidation plants, 4,977,953 tons at concentration mills, 244,026 tons shipped crude to smelters, and 204,362 tons treated at a slag-fuming plant.

Three cyanidation mills treated 75,730 tons of gold ore, which contained 4,281 ounces of gold and 18,260 ounces of silver; the bullion and precipitates produced yielded 3,603 fine ounces of gold and 14,934 ounces of silver, indicating an average recovery of 84 percent of gold and 82 percent of silver. These three mills reported the consumption of 23,247 pounds of sodium cyanide, 27,070 pounds of calcium cyanide, 11,915 pounds of zinc dust, and 259,780 pounds of lime.

Ore treated at straight concentration plants increased from 4,661,117 tons in 1941 to 4,977,953 tons in 1942. The 1942 total comprised 82,758 tons of siliceous ores, 4,319,953 tons of copper ore, 880 tons of lead ore, 2,491 tons of zinc ore, and 571,871 tons of zinc-lead ore.

The East Helena smelter operated continuously in 1942 and treated ores and concentrates chiefly from Montana and Idaho. The Anaconda Copper Mining Co. operated its electrolytic zinc plants at Anaconda and Great Falls throughout 1942. Zinc concentrates were received and treated from most of the Western States but principally from Montana, Idaho, Utah, Washington, Nevada, New Mexico, and California; the concentrates from New Mexico were treated upon a toll basis. In addition to treatment of concentrates from domestic sources, the Anaconda and Great Falls plants treated over 100,000 tons of zinc concentrates from foreign sources, chiefly upon a toll basis, for the accounts of the Metals Reserve Co., United States Smelting, Refining & Mining Co., and American Zinc Co. These foreign concentrates originated at mines in Australia, Canada, Chile, Mexico, and Peru. The Metals Reserve Co. maintains a stock pile of zinc concentrates at Anaconda, which are received into the Anaconda Copper Mining Co. account as smelting capacity permits. Currently the stock pile is equivalent to about a 20-day run. At the beginning of 1942 the plants comprised 4 units at Anaconda and 8

Digitized by Google

units at Great Falls. During the year the capacity was increased 25 percent, and at the beginning of 1943 the Anaconda section had 5 units and the Great Falls 10 units. As of April 1943, the Anaconda and Great Falls sections combined were producing at the rate of approximately 2,750,000 pounds of slab zinc, dross, and oxide per unit per month. At Anaconda the capacity of the copper concentrator was increased 20 percent—rated now as about 16,000 tons per day—and at the smelter an entirely new converter plant was erected.

Details of the treatment of all ores produced in Montana in 1942 are given in the tables that follow.

Mine production of metals in Montana in 1942, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore amalgamated	12,773	956	207			
Ore and old tailings cyanided	239,166	27,061	66,202

BEAVERHEAD COUNTY

Argenta district.—The Ermont Mines, Inc., was again the chief gold producer in the Argenta district. In 1942 the company operated its 100-ton countercurrent cyanide mill until about October 15, when all work stopped. During the 9½ months of activity the mill treated about 11,000 tons of gold ore, equivalent to about one-third of that treated in 1941. The decreased output of ore was due to a shortage of miners. Virtually all the remainder of the district output was lead ore.

Bannack district.—Placer gravels in 1942 continued to be the chief source of gold in the Bannack district. The Ralph E. Davis Syndicate operated its dragline dredge at the Grasshopper Creek placer until May 11, and the Traderhorn Mining & Construction Co. operated its dry-land dredge at the Rimrock placer until April 30.

Bryant district.—A total of 12,863 tons of siliceous tailings, crude lead ore, and old zinc slag was shipped direct to Utah smelters from the Hecla and Greenwood mines in 1942 by L. D. Foreman. Most of the 12,863 tons shipped was old zinc slag (11,382 tons) from the Hecla slag dump and contained about 2.5 percent lead and 10 percent zinc, in addition to the other usual lead blast-furnace slag constituents. The slag was shipped to Tooele and there treated first in the lead blast furnace, followed by treatment in the slag-fuming plant. The remaining production from the district was copper ore shipped crude to Washoe.

Horse Prairie (Colorado) district.—Virtually all the placer output from the Horse Prairie district in 1942 came from the Chinatown property of Associated Placers, Inc., on Colorado and Jeff Davis Creeks and the Golden Leaf property of W. C. McLeod on Jeff Davis Creek. Both operators used dry-land dredges and washed a total of 106,000 cubic yards of gravel. Hoffman & Steele shipped 284 tons of lead ore in 1942 to Midvale (Utah) from the H. & S. mine.

Vipond district.—Most of the production from the Vipond district in 1942 was silver ore shipped to Washoe from the Lone Pine & Argyle property.

BROADWATER COUNTY

Backer district.—The Superior mine was the chief source of lode gold; its output comprised gold ore shipped direct to a smelter and gold ore amalgamated. Most of the placer output came from a dry-land dredge operated in Confederate Gulch by R. G. Woodard.

Beaver district.—The value of the metal production from the Beaver district in 1942 was much lower than in 1941 because the output of gold ore was smaller. Lead ore and zinc-lead ore, both rich in gold, were shipped from the East Pacific and East Pacific Tunnel No. 4 to East Helena and Anaconda zinc concentrator, respectively, and gold ore from the Vosburg property was shipped crude to East Helena. The remainder of the lode output was crude ore shipped direct to smelters and was chiefly gold ore from the Edna No. 2, Custer Group, Iron Age, and Martha Washington properties.

Cedar Plains district.—The M & M Mining Co. was again the leading producer in the district and treated 32,000 tons of gold ore from the Ohio Keating mine in its 100-ton cyanidation-concentration mill. The property, unlike most other gold properties in Broadwater County, was active throughout 1942 and is still active in 1943. The

Digitized by Google

C. G. Gold Corporation operated the Keating mine and its 100-ton flotation concentrator until May 1, 1942, when all work ceased for the duration of the war.

Park district.—The most important lode producer in the Park district was again the Marietta mine, from which gold ore (112 tons) and lead ore (269 tons) were shipped direct to smelters. The output from placer operations continued to be the chief source of gold in the district, but it was less than half that produced in 1941. A. R. Douglas, the outstanding producer in the district, operated a dry-land dredge on Indian Creek until September, when all activity ceased. The Cooley Gravel Co., formerly the chief producer in the district, operated until October 14, when all work ceased.

CASCADE COUNTY

Montana district.—The Montana district reported a substantial decrease in output of gold, silver, lead, and zinc in 1942 compared with 1941. Zinc-lead ore from the Broadwater group treated by the Klies Mining Co. in its 80-ton flotation mill amounted to 23,783 tons compared with 29,190 tons in 1941. The ore treated in 1942 had a higher silver and gold content but a lower zinc and lead content, which explained most of the decrease in the zinc and lead output of the district. In addition to ore from the Broadwater group, the company milled 5,082 tons of silver-lead ore from the Graham and Hollowbush group. The latter group was closed indefinitely on December 31. Silver ore milled by the Lexington Mining Co. from the Big Seven Group represented nearly half of the silver output of the district. In 1942 the company treated about 22,000 tons of silver ore compared with 32,718 tons in 1941 in its 100-ton flotation mill and made high-grade silver concentrates. In addition, 74 tons of lead ore rich in silver were shipped direct to East Helena. The Florence Co. operated the Florence mine throughout 1942 but closed its mill in September; the remainder of the year was spent developing the mine. During the period of operation about 11,000 tons of silver ore were milled in the company 75-ton flotation mill, making lead concentrates. Silver ore from the Star group was treated in the New London Mining Corporation 40-ton flotation mill, making lead concentrates. The Queen Leasing Co. operated the Queen of the Hills mines through March, when the property was closed. The 60-ton flotation mill was dismantled and moved from the property.

DEER LODGE COUNTY

Georgetown district.—The Sentinel Mines, Inc., operated the Holdfast-Southern Cross group from January until August, when all activity stopped. During this period 8,252 tons of gold ore were treated in the company 65-ton countercurrent cyanidation mill, yielding 2,053 ounces of gold and 1,037 ounces of silver.

FERGUS COUNTY

North Moccasin district.—The North Moccasin Mines Syndicate operated its Barnes-King open-cut mine throughout 1942 and treated 54,804 tons of gold ore by cyanidation compared with 75,535 tons in 1941. Gold occurs in porphyry, limestone, and clays, which are carried to the cyanide mill on a conveyor belt and leached.

Digitized by Google

FLATHEAD COUNTY

Hog Heaven district.—The Anaconda Copper Mining Co. operated its Flathead mine throughout 1942, although the rate of output declined considerably during the latter part of 1942. During the year the company shipped 23,024 tons of highly siliceous silver ore crude to Washoe and 4,395 tons of lead ore crude to East Helena. The West Flathead, also owned and operated by the Anaconda Copper Mining Co., produced 448 tons of high-grade silver ore, all of which was shipped direct to Washoe.

GRANITE COUNTY

Boulder district.—High-grade gold ore from the Gold King and Gold Mountain mine was shipped crude to East Helena in 1942 and represented most of the district output.

Dunkleberg district.—Virtually all of the output of the Dunkleberg district in 1942 was zinc-lead ore from the Forest Rose and Wasa mines, both operated by the Forest Rose Syndicate. The Wasa properties are under lease to the Forest Rose Syndicate and are contiguous to the Forest Rose mine. According to the Forest Rose Syndicate, work was started on the Wasa and Monarch properties in 1942, and considerable fine oxide cappings underlaid by sulfide ores were investigated at shallow depth. This work is promising, showing as much as 12-foot widths of fair-grade zinc-lead ore. Roads have been built to connect the properties. An aggregate of 22,500 tons of zinc-lead ore (Forest Rose and Wasa mines), which averaged about 4 percent zinc and 4 percent lead, was treated in 1942 in the Forest Rose 100-ton flotation mill. The output of zinc and lead concentrates produced was nearly double that in 1941.

First Chance district.—Most of the placer gold output in 1942 was recovered from the floating connected-bucket dredge of the Star Pointer Exploration Co., which operated in Bear Gulch. The company operated its electrically powered Yuba dredge from January through October and handled 1,308,700 cubic yards of gravel. Crude gold ore shipped direct to smelters comprised the output from lode mines and came principally from lessee operations on the Mitchell-Mussigbrod and Grant and Hartford groups.

Flint Creek district.—Old tailings from the Granite-Bimetallic mine continued to be the chief source of metal output from the Flint Creek district. In 1942 the Philipsburg Mining Co., operator of the mine, shipped over 66,000 tons of these tailings direct to the Tacoma, Washoe, and East Helena smelters, for flux. The Moorlight Mining Co. operated the True Fissure mine and shipped crude lead and silver ore direct to East Helena and Washoe, respectively, and zinc ore to the Anaconda zinc concentrator. The Marie Leasing Co. operated the Marie mine throughout 1942 and shipped 68 tons of crude lead ore and 1,080 tons of rich silver ore direct to smelters; the ore was extracted concurrently with the mining of manganese ore. Manganese-ore tailings from the Trout mine, which contained gold and silver, were cyanided in a 50-ton cyanide plant; operations were suspended in July.

Rock Creek district.—The only lode production in the Rock Creek district in 1942 was from the MacDonald (Ella) mine.

Digitized by Google

JEFFERSON COUNTY

Cataract district.—The Basin Montana Tunnel Co., although inactive itself in 1942, granted leases for the purpose of cleaning up the Comet 200-ton flotation mill and shipping ore from the Grey Eagle dump. These lessees shipped a total of 793 tons of gold-silver ore and were the largest producers in the district. Other production included crude gold-silver ore from the Crystal, Hope, and Morning Glory mines and lead ore from the Crescent mine.

Clancey district.—Winston Bros. Co. operated its 6-cubic foot electrically driven Yuba bucket dredge in 1942 from January 14 to October 15, when all work was suspended. During the period of operation the bucket dredge washed 1,520,042 cubic yards of gold-bearing gravel compared with 2,157,277 in 1941. The company was again the largest producer of placer gold in Montana. The remainder of the placer output came from operation of a dry-land dredge on Clancey Creek by Jefferson Placers.

Colorado district.—The value of the metal output from the Colorado district in 1942 increased compared with 1941 because of much larger output of base metals. The Monongahela-Mount Washington Mining Co. started operations on its Mount Washington property April 7 and continued the rest of the year. During the operating period, 28,799 tons of zinc-lead ore were treated in the company 150-ton flotation mill, resulting in the production of 1,050 tons of lead concentrates and 1,350 tons of zinc concentrates. The lead concentrates were smelted at East Helena, Mont., and the zinc concentrates at Amarillo, Tex. In addition to the zinc-lead ore milled, the company shipped 329 tons of crude lead ore to East Helena, and a lessee shipped 252 tons from the Mount Washington dump. The company, although active for only 9 months in 1942, was one of the major producers of lead and zinc in the State.

Elkhorn district.—Most of the output from the Elkhorn district in 1942 came from the Elkhorn mine, from which 1,720 tons of silver dump ore were shipped to a smelter.

Montana City district.—Two dry-land dredges treated a total of 10,943 cubic yards of gold-bearing gravel (recovering 168 ounces of gold and 38 ounces of silver) and supplied nearly all the district output in 1942.

Whitehall district.—A lessee operated the Golden Sunlight mine, which was again by far the largest producer in the district, and shipped over 15,000 tons of gold ore crude to Washoe.

Wilson Creek district.—Gold ore shipped crude to a smelter and gold ore amalgamated and concentrated from the Callahan group (Deer Horn) comprised the only output from the Wilson Creek district in 1942.

JUDITH BASIN COUNTY

Barker district.—Virtually all the output of the Barker district in 1942 was derived from the zinc-lead ores of the Block P group, operated by the St. Joseph Lead Co. Rehabilitation work on the Block P mine and 400-ton flotation mill was begun in 1941, and by early 1942 the work was completed and actual mining and milling operations started. During the year the mill treated over 36,000 tons of zinc-lead ore, making about 2,900 tons of lead concentrates and about 2,000 tons of zinc concentrates.

Digitized by Google

LEWIS AND CLARK COUNTY

Dry Gulch district.—The Golden Messenger Corporation operated its Golden Messenger mine until March, treated about 10,000 tons of ore by cyanidation, and recovered 1,446 ounces of gold and 1,568 ounces of silver.

Heddleston district.—The Mike Horse Mining & Milling Co. operated the Mike Horse mine and its flotation mill throughout 1942 and more than doubled the 1941 output of zinc and copper, while the output of lead was increased substantially. The company increased its milling capacity from 150 tons a day to 200 tons and treated nearly 63,000 tons of zinc-lead-copper ore, which made about 4,500 tons of lead-copper concentrates and about 2,800 tons of zinc concentrates. The mill was operated three shifts a day 7 days a week.

Helena district.—Porter Bros. Corporation operated its 6-cubic foot Yuba dredge in 1942 from January 1 to October 18, when work was suspended temporarily. On December 8 the dredge was again active and remained in operation the rest of the year. A total of 1,455,393 cubic yards of gravel was washed in 1942 compared with 1,864,078 in 1941, supplying nearly all the placer gold output in the Helena district. Lode production came from several small mines, including the Court House, Spring Hill, and Whitlatch.

Lincoln district.—The Missoula Lincoln Metals Co. operated a dry-land dredge on the Blue Bird placers from June 1 to August 1 and produced nearly all the placer output of the district in 1942. Crude silver ore from the Silver Egal mine was shipped to East Helena.

Marysville district.—The Martin Mining Co. continued to be the most important producer in the district and in 1942 treated 17,888 tons of old tailings in its 120-ton cyanidation mill. The tailings were mined from the Eck, Brown, and Chevalier ranches by power shovel, hauled to the cyanidation mill, and there roasted, crushed, and cyanided and the gold and silver precipitated. All work was suspended October 5. The Montana Rainbow Mining Co. and individual lessees operated the Drumlummon mine. The production in 1942 comprised 2,117 tons of gold ore, which contained 880 ounces of gold and 3,460 ounces of silver and was shipped crude to East Helena. The company also moved a 160-ton flotation-amalgamation mill from near Libby to the property. The Silver Crescent, Inc., operated the Belmont mine from March 1 to September 5; during this time the company treated 2,594 tons of ore in the 60-ton Drumlummon cyanide mill, which was remodeled in 1941. The company also shipped 177 tons of gold ore crude to East Helena. H. E. Luderer treated gold-silver ore in a 35-ton flotation mill and made 112 tons of lead concentrates, which were shipped to East Helena.

Missouri River district.—The Perry-Schroeder Mining Co. operated its 6-cubic foot Yuba dredge on the Missouri River, 15 miles north of Helena, throughout 1942 and washed 1,869,500 cubic yards of gold-bearing gravel. No platinum was reported recovered in 1942 from this operation.

Rimini district.—The South Dakota Mining Associates acquired control of a large number of mines, dumps, and prospects in the Rimini district in 1942 and shipped test lots of siliceous and lead ore from many of the properties, the more productive being the Bunker Hill, Evergreen, Free Speech, Lexington, Mineral Deposit, and

Digitized by Google

Transit claims. The aggregate production was 354 tons of lead ore and 268 tons of siliceous gold-silver ore.

Scratch Gravel district.—Most of the output from the Scratch Gravel district in 1942 was siliceous dump ore from the Helena mine dump shipped crude to East Helena.

Smelter district.—The slag-fuming plant at East Helena, owned and operated by the Anaconda Copper Mining Co., was active throughout 1942, and the output of zinc-lead fume was considerably greater than in 1941. The company treated 204,362 tons of current slag and old slag from the East Helena lead smelter and produced zinc-lead fume valued at approximately $4,025,000. The American Smelting & Refining Co. re-treated about 5,900 tons of gold-silver-lead-copper slag in 1942.

Stemple district.—The Gould mine, operated by the Standard Silver-Lead Mining Co., was again the leading producer in the district in 1942, although all work was suspended March 1. During the first 2 months of the year the company treated 4,239 tons of gold ore in its 100-ton cyanidation mill and recovered 714 ounces of gold and 5,078 ounces of silver from bullion shipped to the mint. The company also shipped several tons of crude gold ore and some rich cleanings to East Helena. The Swan Sea Mines, Inc., treated about 1,500 tons of gold-silver ore in a concentrating mill, making 120 tons of lead-copper concentrates, which were shipped to East Helena.

LINCOLN COUNTY

Libby district.—Most of the lode output in the Libby district in 1942 came from the Snowshoe group of properties, operated by Snowshoe Mines & Co. The company operated the property from April 12 to November 9 and treated about 880 tons of lead ore in its 60-ton flotation mill, making 102 tons of lead concentrates.

MADISON COUNTY

McCarthy Mountain district.—Mueller Bros. operated the B. B. & I. E. property throughout 1942 and shipped 349 tons of silver-lead ore crude to East Helena; the remainder of the district output was a test lot of gold ore shipped crude to Washoe and a little gold ore amalgamated from the Hidden Treasure mine.

Norris district.—The Boaz mine operated its 50-ton cyanide-concentration mill all of 1942 on company and custom ore. On company account 13,349 tons of ore were treated, yielding 3,719 fine ounces of gold and 2,089 ounces of silver in bullion and 255 tons of gold concentrates containing 2,882 ounces of gold and 1,420 ounces of silver. The Grubstake mine shipped 111 tons of crude gold ore, which contained 293 ounces of gold, to Washoe and 5 tons of gold ore for treatment at the Boaz mill; this property was the second-largest producer in the district in 1942. The Montana Coal & Iron Co. operated the Golconda mine from January 1 to June 23 and shipped crude gold ore to Washoe; after June, all equipment was removed and the property was abandoned. Other producers included the Red Bluff, Madisonian dump, and Heleene mine. Homer Wilson operated a floating connected-bucket dredge (5-cubic foot Yuba) on the Norwegian Placer claim from May to September 8 and washed 265,000 cubic yards of gravel, recovering 489 fine ounces of gold and 59 ounces of silver.

Digitized by Google

Pony district.—Gold ore from the Mammouth mine, which was operated all year by the Liberty Montana Mines Co., continued to be the chief source of metal in the district. The company treated 4,687 tons (17,585 in 1941) in its 120-ton flotation-gravity concentration mill, making 28 tons of gold concentrates and 514 tons of copper concentrates.

Renova district.—The West Mayflower mine, owned and operated by the Anaconda Copper Mining Co., was by far the largest producer in the district, and in 1942 the company shipped to Washoe 10,367 tons of ore, which contained 9,670 ounces of gold and 60,688 ounces of silver.

Rochester (Rabbit) district.—Gold ore from the Thistle mine, lead ore from the Jack Rabbit mine, and copper ore from the Ellen Marshall mine, all shipped crude to smelters, comprised most of the output from the Rochester district in 1942.

Sheridan district.—The Sheridan Gold Mining & Milling Co. remained the largest producer in the Sheridan district in 1942 and operated the Toledo group and Uncle Sam mine. The Toledo group was active during the first 10 months of 1942; then Victoria Mines, Inc., Silverstar, Mont., took over the lease and option held by the Sheridan Gold Mining & Milling Co. During the period of activity at the Toledo group, 1,673 tons of high-grade lead ore and 326 tons of gold ore were shipped crude to smelters; the Uncle Sam mine produced 98 tons of crude gold ore. The Standard Silver Lead Mining Co. operated the Buckeye mine and shipped 497 tons of gold-silver ore to a smelter. Several other small lode mines were active in 1942; most of them shipped crude gold ore to smelters.

Silver Star district.—The Victoria Mines, Inc., was the chief producer in the district in 1942 and treated about 26,000 tons of gold ore in its 125-ton cyanidation mill; in addition, the company shipped 398 tons of rich crude gold-lead ore to East Helena and 476 tons of gold ore to Washoe. The cyanide mill was closed in the fall of 1942 but is expected to reopen to treat base-metal ores from the Toledo group of properties in the Sheridan district. The Green Campbell Mining Co. treated about 8,000 tons of gold ore in its 25-ton amalgamation-concentration mill and ranked second in output in the district. The mill and property were closed in late 1942, but the mill is expected to reopen to treat chrome ore from local producers.

Tidal Wave district.—The output from the district in 1942 came from several small lode mines and was of two classes—gold and lead. The largest producers of gold ore were the Agitator and Carolina mines and the largest producers of lead ore the Last Chance and Keystone mines.

Virginia City district.—In 1942 virtually all the ore produced in the Virginia City district was gold and gold-silver ore shipped crude to smelters. The principal producers were the Prospect, U. S. Grant, Kearsarge, Alameda, Easton, and Bartlett properties. R. E. Davis operated a dry-land dredge in 1942 on Barton Gulch, washed 83,945 cubic yards of gravel, and recovered virtually all the placer gold produced in the district.

Washington district.—The Gold Creek Mining Co. operated its bucket dredge in 1942 until November 1, when all activity was suspended indefinitely. Approximately 400,000 cubic yards of gravel were washed, which yielded 1,445 ounces of fine gold and 263 ounces of

556250—43——27

Digitized by Google

silver. Lode production was crude gold and lead ore shipped direct to smelters.

MINERAL COUNTY

Iron Mountain district.—Zinc-lead ore from the Little Anaconda group was shipped to the Bauer mill (Utah); it comprised the only output from the Iron Mountain district in 1942.

MISSOULA COUNTY

Nine Mile district.—Most of the placer output from the Nine Mile district in 1942 came from operation of a dry-land dredge by the Beaver Dredging Co. from March 3 to June 2, when all placer activity was suspended for the duration of the war. During the operating period 267,000 cubic yards of gravel were treated, yielding 1,696 ounces of gold and 30 ounces of silver.

PARK COUNTY

Emigrant Creek district.—The Emigrant Dredging Co. operated its 10-cubic foot electrically powered Yuba dredge from January 1 until October 15, 1942, when all work was suspended for the duration of the war. During its active period the dredge treated 1,048,668 cubic yards of gravel, which yielded 4,315 ounces of gold and 615 ounces of silver.

New World district.—The McLaren Gold Mines Co. operated its Estelle property and 100-ton flotation mill in 1942 until October 28, with a shut-down between May 21 and July 1. During the active periods in 1942 the mill treated 19,809 tons of gold ore, making 753 tons of copper concentrates (rich in gold), which were shipped to Washoe. All operations were suspended indefinitely after the mill was destroyed by fire on October 28. The Irma Mines, Inc., operated its Irma property until August 15, when Willow Creek Mines, Inc., Montana Operation, took over the property and worked it until December 19 to permit sampling the mine. In 1942 the Irma property produced an aggregate of about 2,500 tons of zinc-lead ore, which was milled in the Irma mill, and 67 tons of crude lead ore, which was shipped direct to East Helena.

Sheepeater (Jardine) district.—The Jardine Mining Co., only operator in the Jardine district in 1942, closed its mine and 225-ton amalgamation-concentration mill in January 1942. A program to develop the arsenic ore bodies in the mine was undertaken October 1, 1942, under contract with the Chemical Warfare branch of the Army.

PHILLIPS COUNTY

Little Rockies district.—The Ruby Gulch Mining Co. worked the Ruby Gulch property in 1942 until the last of August, when operations were suspended indefinitely. During 8 months of activity about 45,600 tons of gold ore were treated in the company 300-ton cyanidation mill. The Little Ben Mining Co. suspended operations at the Little Ben mine in June.

POWELL COUNTY

Finn district.—Ray W. Crumb operated a dry-land dredge in Madison Gulch and produced nearly all the placer output of the Finn district in 1942.

Digitized by Google

Nigger Hill district.—Hopkins & Sons Mining Co. operated the Charter Oak mine throughout 1942 and was the chief producer in the district. The first 7 months of the year were spent in developing the property and building a 50-ton flotation mill. In August the mill was put into operation, and during the rest of the year 573 tons of silver ore were treated, which made 28 tons of lead concentrates. The remainder of the output was ore of several classes shipped crude to smelters and came chiefly from the Lilly group, Evening Star, and Cyclone properties.

Zozell (Emery) district.—The Bonanza mine, operated by the Bonanza Leasing Co. in 1942, was by far the chief source of mineral output in the Zozell district. It yielded 1,706 tons of gold ore shipped crude to a smelter. Other producers in the district were the Hidden Hand, Emma Darling, and Bull Moose properties, from which crude ore was shipped to smelters.

RAVALLI COUNTY

Overwich district.—A dragline dredge was operated by the J. L. Shiely Co., Inc., on Hughes Creek in the Overwich district from April 6 to June 16, 1942.

SANDERS COUNTY

Eagle district.—The Jack Waite mine extends over the State line into Idaho; however, all production in 1942 came from that portion within Montana. The property was operated throughout 1942 by the American Smelting & Refining Co. and produced 22,752 tons of zinc-lead ore containing 19,111 ounces of silver, 3,758,630 pounds of lead, and 1,032,940 pounds of zinc. The ore was milled in the company 300-ton flotation plant and made 2,209 tons of lead concentrates and 819 tons of zinc concentrates. In addition, the mine produced 443 tons of high-grade crude lead ore, which was shipped direct to East Helena. The grade of mill ore treated was lower in 1942 than in 1941. The 300-ton flotation plant, situated in Idaho, was active one shift a day, 6 days a week in 1942.

Revais Creek district.—The Green Mountain Mining Co. operated the Drake property in 1942, treated about 800 tons of ore in its 50-ton flotation mill, and made 32 tons of copper concentrates.

Other districts.—C. N. Franck produced 269 tons of gold ore from the Shoestring No. 1 mine in the Vermillion district in 1942; it was shipped to Washoe. Operators of the Glaucus mine in the Plains district shipped 10 tons of copper ore crude to Washoe.

SILVER BOW COUNTY

Output of all metals except copper from mines in Silver Bow County decreased in 1942 owing to curtailment of operations at all zinc mines of the Anaconda Copper Mining Co. after May 25. The following table gives the output of mines in Silver Bow County, which includes the Butte or Summit Valley district, in 1941 and 1942 and the total from 1882 to the end of 1942.

Digitized by Google

Production of gold, silver, copper, lead, and zinc in Silver Bow County, Mont., 1941–42, and total, 1882–1942, in terms of recovered metals

	Mines producing	Ore (short tons)	Gold (lode and placer) (fine ounces)	Silver (lode and placer) (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)	Total value
1941	[1] 65	4,421,641	29,485	8,993,693	254,863,000	17,260,900	76,140,400	$44,195,725
1942	38	4,753,741	22,381	8,123,788	280,698,000	14,411,000	58,626,000	46,942,464
1882–1942	-------	[2]	1,975,192	525,901,025	[3] 6,147,029	[3] 222,942	[3] 1,539,204	2,465,049,603

[1] Corrected figure.
[2] Figures not available.
[3] Short tons.

Butte or Summit Valley district.—All productive mines of the Anaconda Copper Mining Co. maintained capacity operations during 1942 commensurate with the current supply of available labor. The company-operated zinc mines at Butte were operated until in May, when the labor shortage at both zinc and copper mines became so acute that all zinc mines were closed and the mine labor was transferred to the copper mines. During the remainder of the year only a small production came from company-owned zinc mines, and it was incidental to the mining of copper. The aggregate output from all copper mines, dumps, and tailings piles exceeded that in 1941 by 10 percent. The copper concentrator at Anaconda treated 3,287,817 tons of copper ore from company-owned Butte mines compared with 2,869,051 tons in 1941, and 4,589 tons of mine-water precipitates were treated compared with 4,500 in 1941. In addition the copper concentrator at Anaconda treated 241,526 tons of mine-dump material averaging about 1 percent copper compared with 405,862 tons in 1941, 727,464 tons of Old Works tailings and Upper Old Works tailings averaging slightly over 1½ percent copper, and 16,365 tons of New Works tailings averaging less than 1 percent; crude ore smelted amounted to 18,193 tons, and old tailings totaled 42,268 tons. The North Butte Mining Co. property was reopened in 1942 and operated by the Anaconda Copper Mining Co. under a contract agreement. The output from this property amounted to 46,781 tons of copper milling ore and 55 tons of copper precipitates. During the period of activity at the zinc mines they produced 307,900 tons of zinc-lead ore compared with 472,133 tons in 1941. All ores were treated in the company zinc concentrator at Anaconda. Development work in 1942 at all copper mines comprised 232,748 feet of drifts, 201 feet of shafts, and 19,301 feet of diamond drilling; at all zinc mines, 33,068 feet of drifts, 991 feet of shafts, and 1,607 feet of diamond drilling. Operations were continued throughout 1942 at the Emma mine, leased from the Butte Copper & Zinc Co. by the Anaconda Copper Mining Co. Production amounted to 13,583 tons of zinc-lead ore and 30,286 tons of zinc-lead sulfide concentrates (middlings from the treatment of manganese ore), all treated at the zinc concentrator. Development at the Emma mine comprised 1,263 feet of shafts and 1,882 feet of diamond drilling in the zinc section of the mine and 26,454 feet of drifts and 1,725 feet of diamond drilling in the manganese section. At other manganese mines operated by the Anaconda Copper Mining Co. at Butte, development totaled 3,864 feet of drifts and 479 feet of diamond drilling. It is notable that the total advance of 297,397

Digitized by Google

feet (excluding shafts) in 1942 was higher than in any year of record.

Lessees of the Anaconda Copper Mining Co. operated several company properties; the most productive were the Poulin, which yielded zinc-lead ore containing over 4,000,000 pounds of zinc and nearly a million pounds of lead, and the Black Rock group, which yielded 2,218 tons of silver ore and 46 tons of zinc ore. All lessee operations were on a much smaller scale in 1942 than in 1941.

Highland district.—The Butte Highland Mining Co. operated the Highland group (Tilton) and its 75-ton cyanide mill in 1942 until about April, when the property was closed owing to the low grade of the ore.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN NEVADA

(MINE REPORT)

By CHARLES WHITE MERRILL AND H. M. GAYLORD

SUMMARY OUTLINE

	Page		Page
Summary	415	Mining industry—Continued.	
Calculation of value of metal production	416	Ore classification	420
Mine production by counties	419	Metallurgic industry	420
Mining industry	419	Review by counties and districts	426

SUMMARY

The total value of gold, silver, copper, lead, and zinc recovered from ore, old tailings, and gravels in Nevada decreased 8 percent in 1942 compared with 1941; all five metals except copper decreased in both quantity and value. Copper production—167,326,000 pounds—was the largest in the State's history; in value it exceeded each year since 1929. Higher wages, enlistment of miners in the armed forces, migration of miners to war industries and military construction jobs, rising prices of supplies and equipment and difficulties in obtaining them, increased taxes, and fixed prices for gold and silver were factors in reducing the total output, despite Nevada's great mineral resources and the war demand on many of them. War Production Board Order L–208 of October 8, 1942, terminated activities at some large gold mines (many small and some large had closed previously). Probably base-metal mines obtained some much-needed skilled miners as a result of the order and thereby benefited. There was very little evidence, however, that the order itself had much effect on the 1942 decline in gold production (because of reprieves) or in stimulating base-metal output.

Comparing 1942 with 1941, gold output decreased 19 percent and silver 36 percent in both quantity and value; copper increased 6 percent in quantity and 9 percent in value; and lead decreased 44 percent in quantity and 34 percent in value and zinc 33 percent in quantity and 16 percent in value. Of the total value of the five metals copper comprised 57 percent, gold 29 percent, silver 7 percent, zinc 5 percent, and lead 2 percent.

White Pine County increased its lead over other counties and produced 59 percent of the State total value of the five metals; this county stood first in output of copper and gold. Lincoln County produced 8 percent of the State total value and ranked second to White Pine County; it led in the State in silver, zinc, and lead output.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

Digitized by Google

Yardage figures used in measuring material treated in placer operations are "bank measure"; that is, the material is measured in the ground before treatment.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1938–42

Year	Gold [1]	Silver [2]	Copper [3]	Lead [4]	Zinc [4]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1938	$35.00	[5] $0.646+	$0.098	$0.046	$0.048
1939	35.00	[6] .678+	.104	.047	.052
1940	35.00	[7] .711+	.113	.050	.063
1941	35.00	[7] .711+	.118	.057	.075
1942	35.00	[7] .711+	.121	.067	.093

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.
[2] Treasury buying price for newly mined silver.
[3] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production but excludes value of foreign copper delivered to Metals Reserve Co. for domestic consumption.
[4] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production.
[5] $0.64646464. [6] $0.67878787. [7] $0.71111111.

Mine production of gold, silver, copper, lead, and zinc in Nevada, 1938–42, and total, 1859–1942, in terms of recovered metals

Year	Mines producing [1]		Ore, old tailings, etc. (short tons)	Gold (lode and placer)		Silver (lode and placer)

[1] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.
[2] Compiled by Chas. W. Henderson, supervising engineer, field offices, Denver, Colo. From 1904 (when first satisfactory annual canvass of mine production was made) to 1942, inclusive, the output was as follows: Gold, 13,243,681.51 ounces, valued at $311,547,973; silver, 296,016,916 ounces, $199,767,954; copper, 1,547,231 tons, $440,094,340; lead, 284,544 tons, $33,192,205; zinc, 269,036 tons, $37,359,926; total value, $1,021,962,398.
[3] Figures not available.
[4] Short tons.

Gold.—Gold production in Nevada continued near the 1941 rate through May 1942, but thereafter a decline set in; the September output was about two-thirds that of May. The production curve showed no downward break for October and November but declined

Digitized by Google

somewhat in December, indicating some reaction to War Production Board Order L–208, but general economic conditions overshadowed the Government order in causing the decrease from 1941 in output of gold. The 10 leading gold-producing mines in 1942 supplied 74 percent of Nevada's output, and the 5 leaders contributed 56 percent. By the end of the year, however, operations at all but the leading three had been suspended. The War Production Board permitted Getchell Mine, Inc., to continue because of its byproducts—tungsten and arsenic—and gave limited permission to operate to the Manhattan dredge, because the operators were in a narrow canyon and equipment was subject to destruction by cloudbursts.

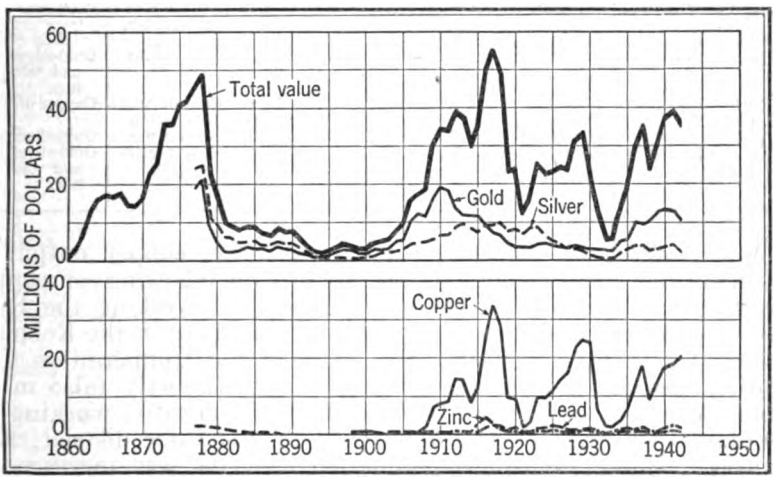

FIGURE 1.—Value of mine production of gold, silver, copper, lead, and zinc and total value in Nevada, 1860–1942.

Ten leading gold-producing mines in Nevada in 1942, in order of output

Rank	Mine	District	County	Rank in 1941	Operator	Source of gold
1	Getchell	Potosi	Humboldt	1	Getchell Mine, Inc.	Gold ore.

9	Northumberland	Northumberland.	Nye	7	Northumberland Mining Co.	Do.
10	Gold Standard	Imlay	Pershing	6	Standard Cyaniding Co.	Do.

Silver.—The 10 leading silver-producing mines in Nevada in 1942, listed in the following table, produced 61 percent of the State total recoverable silver; the first 2 yielded almost one-fourth of the total. As in preceding years, most of the silver was a byproduct of ore

Digitized by Google

mined chiefly for other metals; only 25 percent was derived from straight silver ore.

Ten leading silver-producing mines in Nevada in 1942, in order of output

Rank	Mine	District	County	Rank in 1941	Operator	Source of silver

10	El Dorado-Rover group.	Eldorado Canyon.	Clark	7	El Dorado-Rover Mining Co.	Gold-silver ore and old tailings.

Copper.—Over 98 percent of the recoverable copper output of Nevada in 1942 came from mines operated by the following companies: The Nevada Consolidated Copper Corporation, working the Ruth mine at Ruth and the open pit at Copper Flat (both in the Robinson district, White Pine County); the Consolidated Coppermines Corporation, working the Coppermines group at Kimberly (also in the Robinson district); and the Mountain City Copper Co., working the Mountain City mine at Mountain City (in the Cope district, Elko County). The State copper-production capacity was increased in March when the International Smelting & Refining Co. placed in operation its new 350-ton concentrator at the Copper Canyon Lease property (in the Battle Mountain district, Lander County).

Lead.—Over half the lead produced in Nevada in 1942 was mined in the Pioche district, Lincoln County, where Pioche Nos. 1 and 2 operated by the Combined Metals Reduction Co., the Financier operated by the Salt Lake-Pioche Mining Co. and lessees, and the Prince operated by the Prince Consolidated Mining Co. were the leading properties. Other important producers were the Rip Van Winkle Consolidated Mining Co., Rip Van Winkle mine (in the Merrimac district, Elko County); Hall Bros. Co., Inc., Tybo mine (in the Tybo district, Nye County); and Bristol Silver Mines Co., Bristol Silver mine (in the Jack Rabbit district, Lincoln County).

Zinc.—As in recent years, zinc production was centered in the Pioche district, Lincoln County, where 88 percent of the State total was mined in 1942. The Combined Metals Reduction Co. and the Prince Consolidated Mining Co. were the principal producers. The addition of a slag-fuming plant for recovering zinc from lead blast-furnace slag and from oxidized zinc ore at the Tooele (Utah) plant of the International Smelting & Refining Co. offered a new market to some Nevada miners.

MINING INDUSTRY

Expansion of production at the three large copper mines in Nevada has been the principal cause of the increasing tonnage of ore treated since 1940. Production of copper ore increased 15 percent in 1942 compared with 1941, and the quantity of dry and siliceous ore and old tailings sold or treated declined 26 percent. There was a short-lived revival of old-tailings cyanidation in Nevada, when a 1,000-ton plant went into operation at Millers, Esmeralda County, March 6.

The connected-bucket dredge of the Manhattan Gold Dredging Co. in the Manhattan district, Nye County, was again the largest producer

Digitized by Google

of placer gold and the fourth largest of total gold in the State; the dragline operation in the Silver City district, Lyon County (started January 1, 1941, by the Dayton Dredging Co.), made the second-largest placer-gold and the fifth-largest total gold output in the State in 1942. In addition to these large placer operators, 1 dragline dredge, 2 nonfloating washing plants with mechanical excavators, 2 hydraulic mines, 36 (19 dry) small-scale hand-method mines, and 7 drift mines were in operation. Quicksilver consumption at placer mines was 162 pounds in 1942.

ORE CLASSIFICATION

The following table classifying ores produced in Nevada in 1942 shows that 84 percent of the tonnage (including old tailings) sold or treated was copper ore, 9 percent gold ore and old tailings, 4 percent gold-silver ore and old tailings, 1 percent each zinc-lead ore and silver ore, and the remainder zinc ore, lead ore, and lead-copper ore.

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore and old tailings sold or treated in Nevada in 1942, with content in terms of recovered metals

Source	Material sold or treated		Gold	Silver	Copper	Lead	Zinc

[1] Includes 6,172,600 pounds from precipitates.

METALLURGIC INDUSTRY

Of the 9,383,379 tons of lode material from Nevada sold or treated during 1942, 85 percent went to concentrating mills, 13 percent to amalgamation and cyanidation mills, and 2 percent to smelters; of the total, less than 1 percent was old tailings—all amalgamated, cyanided, or smelted. Flotation was employed at concentration mills to the virtual exclusion of gravity concentration. Of the gold recovered as bullion, cyanidation supplied 94 percent and amalgamation 6 percent; of the silver recovered as bullion, 99.5 percent was derived by cyanidation and 0.5 percent by amalgamation. The total quantity of crude ore and old tailings shipped to smelters in 1942 declined 29 percent compared with 1941.

Digitized by Google

The new 350-ton flotation mill built by the International Smelting & Refining Co. at the Copper Canyon mine in the Battle Mountain district, Lander County, began operation in March 1942. The year 1942, however, witnessed suspension of operations at many mills, particularly after promulgation of Order L–208 by the War Production Board.

Quicksilver consumed in Nevada in 1942 at mills using amalgamation totaled 930 pounds in recovering 8,521 ounces of gold and 7,239 ounces of silver from 89,857 tons of material.

Data obtained on cyanide consumption in 1942 at Nevada mills are nearly complete. In the treatment of 796,193 tons of ore, 36,968 tons of old tailings, and 200 tons of concentrates, 389,867 pounds of 91-percent sodium cyanide and 1,490,526 pounds of commercial-grade calcium cyanide (50-percent NaCN equivalent) were used, with a recovery of 104,984 ounces of gold and 1,213,552 ounces of silver; in terms of 98-percent NaCN the consumption was 1,092,401 pounds, or 1.31 pounds to the ton of material treated compared with 0.98 pound in 1941.

Mine production of metals in Nevada in 1942, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated	Gold	Silver	Copper	Lead	Zinc
	Short tons	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*	*Pounds*

Total, placers		47,354	19,980			
		295,112	3,723,435	167,326,000	10,752,000	20,394,000
Total, 1941		366,403	5,830,238	157,822,000	19,246,000	30,258,000

All of Nevada's custom cyanide mills suspended operations during 1942. The leading ones were operated by the Dayton Consolidated Mines Co., Silver City, Lyon County; Adelaide Crown Mines, Gold Run district, Humboldt County; Silver State Milling Corporation, Westgate, Churchill County; and Ohio Mines Corporation, Gold Point, Esmeralda County. Most of these mills received the major part of their mill feed from mines controlled by the mill operators. The 500-ton selective-flotation mill, operated by the Combined Metals Reduction Co. at Pioche, Lincoln County, treated zinc-lead and zinc ores upon a custom basis for several neighboring mines and also milled company zinc-lead ore. The Nevada Consolidated Copper Corporation treated all the copper ore produced by the Consolidated Coppermines Corporation upon a contract basis, in addition to milling its own ore. The Nevada Consolidated Copper Corporation also operated the McGill copper smelter, which was Nevada's only smelter and the most important metallurgical plant in the State.

[1] Only those districts shown separately for which Bureau of Mines is at liberty to publish figures; other producing districts listed in footnote 8 and their output included under "Other districts."

[2] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

[3] Source of total silver as follows: 3,703,455 ounces from lode mines and 19,980 ounces from placers.

[4] Tonopah district lies in both Esmeralda and Nye Counties.

[5] Battle Mountain district lies in both Humboldt and Lander Counties.

[6] Output from property not classed as a "mine."

[7] Includes 6,172,600 pounds of copper from precipitates.

[8] Includes following districts: Dixie Valley and Sand Springs in Churchill County; Dolly Varden in Elko County; National and Varyville in Humboldt County; Pine Grove in Lyon County; and Millett in Nye County.

Digitized by Google

CHURCHILL COUNTY

The Silver State Milling Corporation, reorganized successor to the Westgate Mining & Milling Corporation, discontinued its custom-cyanide-mill operations at Westgate early in 1942. Thus, the operators of a number of local properties in Churchill County were left without a profitable market for their ores.

Fairview district.—Lessees shipped lead ore to a smelter from the Chalk Mountain mine during 1942. Several groups of lessees worked the Nevada Hills mine; 1,253 tons of gold-silver ore shipped to custom cyanide mills yielded 159 ounces of gold and 15,366 ounces of silver.

Wonder district.—Erwin & Wauchope operated the Nevada Wonder mine from January 1 to June 30, 1942; 1,671 tons of gold-silver ore shipped to a custom-cyanide mill yielded 199 ounces of gold and 14,993 ounces of silver.

CLARK COUNTY

Eldorado Canyon district.—The El Dorado-Rover Mining Co. operated the Quaker City, Magnolia, Crown, and Nevada Eagle claims from January 1 to December 8, 1942; 25,587 tons of gold-silver ore and 530 tons of old tailings were treated in the company 150-ton cyanide mill; cyanide precipitates contained 2,641 ounces of gold and 123,482 ounces of silver, and 33 tons of concentrates shipped to a smelter contained 281 ounces of gold, 7,103 ounces of silver, and 963 pounds of lead. The Diamond Gold Mining Co. operated the Techatticup and Jubilee mines from January 1 to December 1; ore was treated in a 200-ton cyanide mill. W. W. Hartman operated the Wall Street mine throughout the year; gold ore was treated in a 60-ton amalgamation-flotation mill, and the resulting concentrates were shipped to a smelter.

Yellow Pine (Goodsprings) district.—J. Jacobson shipped oxidized zinc ore from the Green Monster mine to a smelter during 1942. The Defense Metals Co. shipped lead and zinc-lead ores from the Hoosier mine. Hammons & Reed and the Ingomar Mining Co., Inc., operated the Ingomar group; 176 tons of zinc-lead ore containing 27,637 pounds of lead and 106,738 pounds of zinc were shipped to a smelter. The Defense Metals Co. and R. K. Hamilton worked the Root Zinc mine during 1942; shipments consisted of 89 tons of lead ore containing 770 ounces of silver and 50,308 pounds of lead; 102 tons of zinc ore containing 10,248 pounds of lead and 82,170 pounds of zinc; and 29 tons of zinc-lead ore containing 8,193 pounds of lead and 7,501 pounds of zinc. L. F. Jacobson shipped 169 tons of zinc-lead ore containing 28,606 pounds of lead and 85,754 pounds of zinc from the Sultan mine between May 20 and October 1, when the smelting company ceased buying the ore and the operation was discontinued. H. C. Kennedy operated the Whale mine from March 19 to December 31; 44 tons of zinc ore shipped to a smelter contained 1,580 pounds of lead and 30,099 pounds of zinc. The principal product of the mine, however, was vanadium. The Yellow Pine Lease shipped zinc ore from the Yellow Pine mine to a smelter.

ELKO COUNTY

Contact district.—The Marshall Mining Co. operated the Delano and Allen mines as a unit from April 1 to December 31, 1942; 605

Digitized by Google

tons of copper ore containing 10 ounces of gold, 895 ounces of silver, and 56,997 pounds of copper were shipped to a smelter.

Cope (Mountain City) district.—The Mountain City Copper Co. (third-largest copper producer in Nevada) was active throughout 1942; part of the ore was treated in the company 400-ton flotation mill, and high-grade copper ore was shipped for direct smelting.

Delano district.—Lessees on the Cleveland mine shipped 192 tons of lead ore containing 1 ounce of gold, 4,655 ounces of silver, 1,592 pounds of copper, 58,823 pounds of lead, and 1,198 pounds of zinc during 1942. Lead ore was produced at the Net mine.

Dolly Varden district.—The International Smelting & Refining Co. carried on development at the Victoria mine from July to December, 1942; copper ore produced during this work and by a lessee was shipped to a smelter.

Gold Circle district.—Percy Collins operated the Miners Gold mine from July 1 to November 1, 1942; 205 tons of gold-silver ore were shipped to a custom cyanide mill, where 101 ounces of gold and 1,890 ounces of silver were recovered.

Jarbidge district.—A. M. Ross recovered 97 ounces of gold and 75 ounces of silver from the treatment of 350 tons of ore mined at the O. K. mine in 1942.

Lime Mountain district.—Lime Mountain Consolidated operated the Lime Mountain mine from May 4 to September 30, 1942; 686 tons of ore shipped to a smelter contained 173 ounces of gold, 824 ounces of silver, 22,186 pounds of copper, and 28,319 pounds of zinc.

Merrimac (Lone Mountain) district.—The Rip Van Winkle Consolidated Mining Co. treated 12,416 tons of lead ore in the company flotation mill and shipped to a smelter 1,137 tons of lead concentrates (containing 23 ounces of gold, 162,322 ounces of silver, 20,745 pounds of copper, and 1,505,103 pounds of lead) and 938 tons of zinc concentrates (containing 5 ounces of gold, 6,372 ounces of silver, 8,352 pounds of copper, 17,874 pounds of lead, and 932,347 pounds of zinc).

Spruce Mountain (Black Forest) district.—Lessees operated the Black Forest mine from January 1 to July 1, 1942; 141 tons of lead ore containing 1 ounce of gold, 1,710 ounces of silver, and 41,176 pounds of lead were shipped to a smelter. E. Parker worked the Humbug mine from January 1 to July 1 and shipped to a smelter 44 tons of lead ore containing 1 ounce of gold, 201 ounces of silver, 509 pounds of copper, and 13,160 pounds of lead.

Warm Creek (Polar Star) district.—Turner & Stoddard shipped to a smelter 312 tons of oxidized zinc ore (containing 6 ounces of silver and 85,034 pounds of zinc) from the dumps of the Polar Star mine between May 2 and June 22, 1942.

ESMERALDA COUNTY

Divide district.—Various lessees on the Divide mine shipped 812 tons of ore containing 430 ounces of gold and 5,929 ounces of silver during 1942.

Dyer district.—J. A. Molini & Son operated the Green Monster mine from March 1 to October 31, 1942; 46 tons of silver ore shipped to a smelter contained 2,496 ounces of silver and 2,996 pounds of lead.

Goldfield district.—Gold ore produced by various sets of lessees on the Goldfield Consolidated Mines Co. property was shipped to a

Digitized by Google

smelter during 1942; 2,269 tons of gold ore contained 1,192 ounces of gold, 503 ounces of silver, and 1,414 pounds of copper.

Hornsilver (Gold Point) district.—The Ohio Mines Corporation suspended operations of the Ohio group mine and the custom cyanide mill at the property during 1942.

Silver Peak district.—Price & Kunde worked the Francis mine and shipped ore to a smelter. E. L. Cord, operating as the Prescott Lease, worked the Mary mine from January to April 1942, when the lease was quit-claimed; 24,943 tons of ore treated in the company 350-ton flotation-cyanidation-leaching plant yielded bullion containing 5,213 ounces of gold and 1,674 ounces of silver, and 354 tons of ore shipped to a smelter contained 482 ounces of gold, 285 ounces of silver, and 1,109 pounds of copper; a small part of the production was the result of lease operation. Desert Silver, Inc., worked the Nivloc mine, leading silver producer in the State since 1938; the ore was treated in the company 175-ton cyanide mill.

Tonopah district.—In 1942 the Bradshaw Syndicate, Inc., completed construction of a 1,000-ton cyanide plant, designed to treat tailings at Millers. Operations began March 6 and were continued by the company until June, when Willow Creek Mines, Inc., took over the management. In all, 56,600 tons of old tailings yielding 230 ounces of gold and 17,767 ounces of silver were treated; work was stopped before the end of the year.

EUREKA COUNTY

Cortez district.—Lessees operated the Roberts group in 1942; 694 tons of gold-silver ore shipped to a smelter contained 158 ounces of gold, 5,993 ounces of silver, 1,135 pounds of copper, and 24,763 pounds of lead. Lessees operating the Ventura and Maid Queen mines shipped to a smelter 383 tons of ore containing 293 ounces of gold and 605 ounces of silver.

Eureka district.—Eureka Corporation, Ltd., operated the Oswego mine intermittently between January and October 1942; 342 tons of ore shipped to a smelter yielded 157 ounces of gold and 155 ounces of silver. Silver Rock Mines, Inc., worked the Wynona mine from January 1 to October 2 and shipped to a smelter 220 tons of silver ore containing 5 ounces of gold and 7,829 ounces of silver.

Lynn district.—C. E. and I. H. Lee operated the Gold Coin No. 1 mine on Sheep Creek from March 10 to July 27, 1942; 1,200 cubic yards of gravel treated by ground sluicing yielded 116 ounces of gold and 7 ounces of silver.

HUMBOLDT COUNTY

Awakening (Slumbering Hills) district.—Lessees operated the Alabama mine during 1942; 339 tons of ore treated by amalgamation yielded 58 ounces of gold and 15 ounces of silver, and 59 tons of ore shipped to a custom cyanide mill yielded 19 ounces of gold and 33 ounces of silver. Austin Bros. Gold Mining Co. worked the Jumbo mine from May 17 to November 11; 1,135 tons of ore treated in the company 25-ton amalgamation mill yielded 206 ounces of gold and 144 ounces of silver.

Barrett Springs (Ten-mile) district.—West Coast Mines, Inc., operated the Pansy Lee mine during the early months of 1942; gold-

Digitized by Google

silver ore was treated in the company 150-ton flotation mill, and the resulting lead concentrates were shipped to a smelter. The King Gold mine was active.

Gold Run (Adelaide) district.—Adelaide Crown Mines operated the Adelaide Crown mine from January 1 to December 7, 1942; in addition to treating ore from this mine, the company treated 1,556 tons of custom ore from 12 shippers.

Potosi district.—Getchell Mine, Inc., operated the Getchell mine throughout 1942. Oxidized ores (treated by cyanidation without roasting) were exhausted in September, and thereafter all ore was given a roast before cyanidation; additions were made to the roasting plant for the recovery of arsenic. In addition, a 250-ton scheelite flotation plant was installed, operation of which began in September.

LANDER COUNTY

Battle Mountain district.—Symanzik & Wrobel worked the Armour mine from March 1 to December 16, 1942; 2,864 tons of silver ore shipped to a smelter contained 185 ounces of gold, 30,262 ounces of silver, and 217,323 pounds of lead. The International Smelting & Refining Co. started operation of its newly constructed 350-ton flotation mill at the Copper Canyon mine early in 1942 and shipped copper ore and copper concentrates to a smelter. Broyles & Wilson worked the Independence mine the entire year and shipped to a smelter 555 tons of gold-silver ore containing 404 ounces of gold and 10,889 ounces of silver. Franzini & Macdonald worked the Palisades-Pinnacle group of claims from June 1 to November 15 and shipped to a smelter 226 tons of gold-silver ore containing 26 ounces of gold, 2,588 ounces of silver, and 8,895 pounds of lead.

Bullion district.—Willow Creek Mines, Inc., acting as manager for the Consolidated Goldacres Co., operated the Goldacres mine from March 7 to December 31, 1942, except for a short shut-down caused by War Production Board Order L–208; ore was treated by cyanidation. S. Dunham operated the Gold Quartz mine. The Little Gem Operating Co. shipped copper ore and flotation copper concentrates from the Little Gem mine.

New Pass district.—New Pass Mines worked the New Pass mine from January 1 to July 1, 1942; ore was treated in a 25-ton amalgamation mill. W. H. Smith worked the Thomas W. mine from January 1 to December 15; 315 tons of ore treated in a 5-stamp mill yielded 146 ounces of gold and 23 ounces of silver.

LINCOLN COUNTY

Groom district.—The I. M. C. Corporation and D. Sheahan operated the Groom mine during 1942; a 50-ton concentration-flotation mill was constructed, and lead ore and lead concentrates were shipped to a smelter.

Jack Rabbit (Bristol) district.—The Bristol Silver Mines Co. operated the Bristol Silver mine throughout 1942 and shipped ore to a smelter.

Pennsylvania district.—Crowe, Phelps & Johnston worked the Pennsylvania mine from January 1 to June 20, 1942; 46 tons of ore shipped to a smelter contained 54 ounces of gold and 564 ounces of silver.

Digitized by Google

Pioche district.—Amalgamated Pioche Mining & Smelting Corporation and a lessee shipped to a smelter silver ore, lead ore, and gold-silver old tailings from the Amalgamated Pioche mine. The Salt Lake-Pioche Mining Co. Apex and Financier mines were worked by lessees, who shipped lead ore to smelters; C. E. Bleak operated the Apex and W. A. Free the Financier. Ely Valley Mine worked the Ely Valley mine throughout 1942 and shipped zinc ore to the Combined Metals Reduction Co. custom mill at Pioche. Lessees worked the Nevada Volcano mine and shipped lead ore to a smelter. The Combined Metals Reduction Co. worked the Pioche Nos. 1 and 2 mines and treated the zinc-lead ore in the company mill at Pioche, except for a small quantity that was shipped to the company mill at Bauer, Utah. The Prince Consolidated Mining Co. shipped zinc ore to the Pioche custom mill of the Combined Metals Reduction Co. throughout the year and a small quantity of lead ore to a smelter. Hall Bros. Co., Inc., shipped gold-silver ore from the Raymond Ely mine to a smelter during January and February; 1,406 tons of ore yielded 57 ounces of gold and 6,366 ounces of silver. Pioche Mines Consolidated, Inc., operated the Wide Awake mine through lessees from January 1 to September 30; lead ore was shipped to a smelter.

LYON COUNTY

Silver City district.—The Dayton Consolidated Mines Co. operated the Dayton mine from January 1 to October 15, 1942, and treated, in the company cyanide plant, 5,050 tons of ore which yielded 1,526 ounces of gold and 8,067 ounces of silver. Ore from nearby mines operated by this company and 5,973 tons of ore received from 94 shippers upon a custom basis were treated at the mill. T. S. Franklin shipped ore from the Haywood mine to a custom cyanide mill. The Gold Rock Mining Co. shipped ore from the Silver King mine to a custom cyanide mill.

Yerington district.—Lessees worked the Mason Valley mine throughout 1942 and shipped to a smelter 551 tons of copper ore containing 3 ounces of gold, 113 ounces of silver, and 109,072 pounds of copper.

MINERAL COUNTY

Bell (Simon) district.—Lessees worked the Olympic mine from January 1 to July 1, 1942, and shipped 88 tons of ore to a custom cyanide mill; 83 ounces of gold and 68 ounces of silver were recovered. Costa & Evansen worked the Simon Lead mine and shipped to a smelter 1,677 tons of lead ore containing 19 ounces of gold, 9,313 ounces of silver, 24,110 pounds of copper, 217,926 pounds of lead, and 199,924 pounds of zinc.

Garfield district.—The Mabel mine was operated by lessees in 1942; 23 tons of gold-silver ore shipped to a custom cyanide mill yielded 4 ounces of gold and 105 ounces of silver, and 1,434 tons of gold-silver ore shipped to a smelter contained 130 ounces of gold and 5,124 ounces of silver.

NYE COUNTY

Manhattan district.—E. J. Hyde operated the Big Four mine in 1942; 100 tons of ore treated by amalgamation yielded 128 ounces of gold and 58 ounces of silver. J. L. Sullivan worked the Pathfinder

Digitized by Google

mine from January 1 to October 31 and panned 500 pounds of ore yielding 58 ounces of gold and 23 ounces of silver. J. Farrell and R. Graham shipped several lots of ore for treatment by amalgamation, cyanidation, and smelting; 128 tons of ore amalgamated yielded 134 ounces of gold and 56 ounces of silver, 12 tons of gold ore cyanided yielded 10 ounces of gold and 3 ounces of silver, and 8 tons of gold ore smelted yielded 12 ounces of gold and 25 ounces of silver. The Manhattan Gold Dredging Co. (largest producer of placer gold in the State since 1939) operated throughout 1942; its electric connected-bucket dredge was equipped with 108 9½-cubic foot buckets. This company was granted limited permission to operate after the issuance of War Production Board Order L–208 because the dredge was situated in a narrow canyon and subject to danger of cloudburst floods.

Morey district.—V. J. Barndt worked the Morey mine from January 1 to June 30, 1942, and shipped ore to smelters; 279 tons of silver ore yielded 15 ounces of gold and 5,441 ounces of silver, and 8 tons of lead ore contained 2 ounces of gold, 1,427 ounces of silver, and 2,839 pounds of lead.

Northumberland district.—The Northumberland Mining Co. operated the Northumberland mine from January 1 to October 15, 1942; 79,445 tons of ore treated in the company 300-ton cyanide mill yielded 10,145 ounces of gold and 8,577 ounces of silver.

Tonopah district.—The Tonopah Belmont Syndicate operated the Tonopah Belmont mine from January 1 to October 7, 1942; 177 tons of gold-silver ore containing 55 ounces of gold and 5,209 ounces of silver were shipped to a smelter. A shipment of 16 tons of gold-silver ore from the Tonopah Extension mine to a smelter contained 54 ounces of gold and 5,506 ounces of silver; the long-idle 500-ton cyanide plant at the property was totally destroyed by fire October 23. Several sets of lessees worked parts of the Tonopah Mining Co. of Nevada property throughout 1942 and shipped gold-silver ore to a smelter. Gold-silver ore containing 572 ounces of gold and 50,388 ounces of silver was shipped to a smelter from the West End mine.

Tybo district.—Hall Bros. Co., Inc., and J. C. Jepson worked the Tybo mine during 1942 and shipped ore and old tailings to a smelter; 104 tons of gold-silver ore contained 7 ounces of gold, 823 ounces of silver, and 8,539 pounds of lead; 210 tons of silver ore contained 9 ounces of gold and 1,619 ounces of silver; and 6,408 tons of lead old tailings contained 612 ounces of gold, 22,389 ounces of silver, and 1,042,524 pounds of lead.

PERSHING COUNTY

Imlay district.—The Standard Cyaniding Co. worked the Gold Standard and Lally mines in 1942 until operations were suspended as a result of War Production Board Order L–208.

Jersey district.—I. D. Kelly worked the Rex mine from June 1 until the end of 1942; 96 tons of lead ore containing 5 ounces of gold, 2,395 ounces of silver, 789 pounds of copper, 34,313 pounds of lead, and 10,892 pounds of zinc were shipped to a smelter.

Staggs district.—The Twin Buttes Mining Syndicate constructed a 15-ton gravity-concentration mill between January 1 and May 10,1942, after which production was carried on until the end of the year.

Digitized by Google

STOREY COUNTY

Comstock district.—Lessees shipped 152 tons of gold ore from the Chollar mine to a custom cyanide mill in 1942; 113 ounces of gold and 1,435 ounces of silver were recovered. A large quantity of company gold ore was treated in the 100-ton flotation mill at the Consolidated Virginia mine between January 1 and October 24; the concentrates were shipped to a custom cyanide mill. Sutro Tunnel Coalition, Inc., worked the Crown Point and Yellow Jacket mines the entire year. The Dayton Consolidated Mines Co. and lessees shipped gold ore from the Justice mine to the company custom cyanide mill at Silver City; the same company operated the Keystone and New York mines from January 1 to October 8 and treated ore in its cyanide mill. The Consolidated Chollar Gould & Savage Mining Co. operated its open pit at the Overman mine from January 1 to December 7; 141,505 tons of ore treated by cyanidation yielded 11,752 ounces of gold and 94,017 ounces of silver.

WHITE PINE COUNTY

Aurum district.—The Grand Deposit Mining Co. worked the Grand Deposit mine from June 15 to December 31, 1942; 280 tons of oxidized zinc ore containing 137,614 pounds of zinc were shipped to a zinc slag-fuming plant. The company received a $10,000 development loan from the Reconstruction Finance Corporation in November.

Bald Mountain district.—E. R. Wagner shipped 290 tons of gold ore, containing 43 ounces of gold, 596 ounces of silver, and 11,148 pounds of copper, from the Pioneer mine to a smelter in 1942.

Granite district.—Lessees worked the Stinson mine during 1942; 4 tons of ore treated by amalgamation yielded 10 ounces of gold and 2 ounces of silver, and 47 tons of ore shipped to a smelter contained 77 ounces of gold and 22 ounces of silver.

Osceola district.—The Gilded Age Mining Co. worked the Gilded Age mine from January 1 to October 15, 1942; 3,388 tons of ore containing 3,359 ounces of gold and 1,220 ounces of silver were shipped to a smelter.

Robinson district.—The Nevada Consolidated Copper Corporation, which had been the operating subsidiary of the Kennecott Copper Corporation in Nevada for many years, merged with the parent corporation and became known as the Kennecott Copper Corporation, Nevada Mines Division, at the end of 1942. This corporation, which operated the Ruth mine at Ruth, the open pit at Copper Flat, the McGill flotation concentrator (daily capacity, 20,000 tons) and the McGill copper smelter, both at McGill, was the largest industrial organization in Nevada. As well as being the State's leading copper producer, the company stood second in gold and eighth in silver output. The Consolidated Coppermines Corporation, second-largest copper producer and third-largest gold producer in the State in 1942, was active throughout the year; copper ore mined on company account was shipped to the McGill concentrator, and small quantities of high-grade copper ore and zinc-lead ore were shipped for direct smelting. C. Caviglia shipped gold ore from the Chainman mine to a smelter. S. M. Robison shipped zinc-lead ore and zinc ore from the Columbia mine to smelters during the year. Lessees on the Cuba mine shipped 4,440 tons of gold-silver ore containing 362 ounces of gold and 18,669 ounces of silver to a smelter during 1942. Benson Bros. shipped 30

Digitized by Google

tons of lead ore, containing 1 ounce of gold, 334 ounces of silver, and 21,667 pounds of lead, from the Goldenrod mine to a smelter. Gold ore from the Hayes mine was shipped to a smelter. A lessee worked the Jupiter mine from January 1 to November 16 and shipped gold ore to a smelter. Lessees worked the Phoenix mine from July 1 to December 31; 536 tons of ore shipped to a smelter contained 134 ounces of gold and 1,048 ounces of silver. The Ely Gold Mining Co. shipped gold-silver ore and zinc ore from the Revenue mine to a smelter. The Willard Leasing Co. worked the Willard mine from May to the end of the year; 675 tons of oxidized ore containing 694,913 pounds of zinc were shipped for treatment.

Taylor district.—Lessees worked the Gore mine; 5,711 tons of silver ore containing 113 ounces of gold and 62,709 ounces of silver were shipped to a smelter. Lessees worked the Mineral Farm No. 1 mine and shipped to a smelter 394 tons of silver ore containing 9 ounces of gold and 4,742 ounces of silver.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN NEW MEXICO

(MINE REPORT)

By CHAS. W. HENDERSON

SUMMARY OUTLINE

	Page		Page
Summary	439	Mining industry	444
Calculation of value of metal production	440	Ore classification	444
Mine production by counties	443	Metallurgic industry	445
		Review by counties and districts	448

SUMMARY

Production of both copper and zinc in New Mexico in 1942 was larger in quantity than in any previous year; that of lead was slightly less than in 1941 but greater than in 1940. The output of gold decreased 57 percent and that of silver 49 percent, in both quantity and value. The total value of the recovered output of the five metals was $29,542,885 in 1942, compared with $25,471,416 in 1941. Copper represented 66 percent and zinc 29 percent of the total value in 1942.

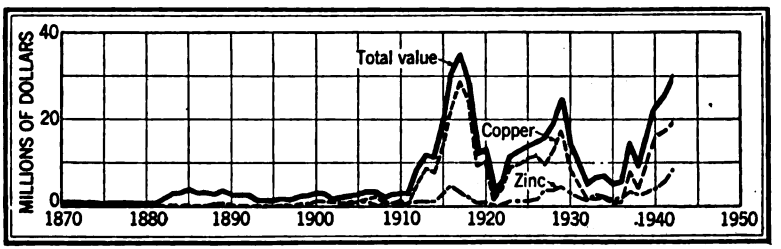

FIGURE 1.—Value of mine production of copper and zinc and total value of gold, silver, copper, lead, and zinc in New Mexico, 1870-1942. The value of gold, silver, and lead produced annually has been relatively small.

Production of gold, silver, copper, lead, and, more particularly, zinc in 1942 was affected by several factors, all precipitated by the war. In an effort to stimulate the production of copper, lead, and zinc the Government, through its agency, the Metals Reserve Co., announced that effective February 1, 1942, premium prices of 5 cents per pound for copper and 2¾ cents per pound for both lead and zinc would be paid for these metals produced in excess of fixed basic quotas. The ceiling prices for these metals on that date (and they have so remained through June 1943) were: Copper, electrolytic, 11.775 cents per pound f. o. b. Atlantic seaboard refineries; lead, 6.50 cents (New York); zinc, 8.25 cents (St. Louis). The quota for each mining company or mine was based upon the 1941 output. Some of the mines in New Mexico that received basic quotas on their 1941 production have since received, by negotiation with the Metals Reserve Co., a reduction in the quota tonnage. On December 1,

Digitized by Google

1942, arrangements for additional premium payments for over-quota metal output were announced by the Metals Reserve Co. Operators who could argue their inability to maintain present rate of production without loss of money or who could assure additional output were eligible for these additional Government subsidies for copper in several steps of 5 cents a pound for each step, or for lead and zinc in steps of 2¾ cents a pound.

War Production Board Gold Mining Limitation Order L–208, issued October 8, 1942, has been widely assigned in the Western States as the outstanding single cause for the marked decrease in production of gold in 1942. An analysis of gold lode and placer operations in New Mexico in 1942 disclaims this conception for New Mexico. All gold lode operations that would have been affected by this order ceased operations during the first 6 months of 1942. Of the three producing dredging operations in New Mexico in 1942, two were forced to cease operating by the order; the other stopped production in April 1942. Factors forcing the closure of these gold properties were many, and their effect was not confined to 1942. Many operators began to feel the acute scarcity of skilled labor in 1941. Higher wages in war-material factories and at army cantonments, rising operating costs, difficulty of obtaining replacement equipment, and the drain on company personnel imposed by the selective service were all responsible for the early closing of the gold properties.

These factors confronted gold-mine operators as early as January 1941, and the complexity of government priorities regulations also had their effect upon zinc, lead, and copper operations in New Mexico in 1942. Operators were confronted with increasing demands for metals and decreasing supply of labor. Marked absenteeism at the larger operations in 1942 forced the companies to carry 30 percent more employees on the rolls to insure a near complement of men for each shift. At the end of 1942 the mine operators in New Mexico found themselves facing the problem of meeting increasing demand with insufficient labor in 1943.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1938–42

Year	Gold [1]	Silver [2]	Copper [3]	Lead [4]	Zinc [4]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1938	$35.00	[5] $0.646+	$0.098	$0.046	$0.048
1939	35.00	[6] .678+	.104	.047	.052
1940	35.00	[7] .711+	.113	.050	.063
1941	35.00	[7] .711+	.118	.057	.075
1942	35.00	[7] .711+	.121	.067	.093

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.
[2] Treasury buying price for newly mined silver.
[3] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production but excludes value of foreign copper delivered to Metals Reserve Co. for domestic consumption.
[4] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production.
[5] $0.6464464. [6] $0.67878787. [7] $0.71111111.

Digitized by Google

The following table shows the number of mines in New Mexico producing gold, silver, copper, lead, and zinc and their annual output of ore and metals from 1938 to 1942; also the total production from 1848 to 1942. The report of this series for 1929 (chapter of Mineral Resources of the United States, 1929, pt. 1, pp. 729–759) gives the yearly production of each important metal-producing district in New Mexico from 1904 to 1929, inclusive. Subsequent records year by year may be found in annual issues of Mineral Resources and Minerals Yearbook.

Mine production of gold, silver, copper, lead, and zinc in New Mexico, 1938–42, and total, 1848–1942, in terms of recovered metals

Year	Mines producing		Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1938	166	164	2,414,857	43,050	$1,506,750	1,229,860	$795,061
1939	214	168	4,977,375	36,979	1,294,265	1,400,878	950,899
1940	164	179	7,089,903	35,943	1,258,005	1,407,839	1,001,130
1941	145	103	7,530,226	27,845	974,575	1,328,317	944,581
1942	78	48	8,221,512	11,961	418,635	676,170	480,832

1940	2,928	102,480	263	187	102,667						

Gold.—Mine production of gold in New Mexico decreased from 27,845 fine ounces in 1941 to 11,961 ounces in 1942. The principal gold-producing districts in 1942 were: Central, Grant County, which contributed 34 percent of the State output of recovered gold; Mogollon, Catron County, 28 percent; Steeple Rock, Grant County, 12 percent; Lordsburg, Hidalgo County, 11 percent; Las Animas, Sierra County, 5 percent; and Pinos Altos, Grant County, 3 percent. Dry and siliceous ores yielded 45 percent of the State total gold; copper ore, 40 percent; lead, zinc, zinc-lead, and lead-copper ores, over 4 percent; and placers, over 10 percent.

556250—43——29

Digitized by Google

Silver.—Mine production of silver in New Mexico was 676,170 fine ounces in 1942 compared with 1,328,317 ounces in 1941. The Central district contributed 33 percent of the State total in 1942, Mogollon 31 percent, Lordsburg 13 percent, Steeple Rock 9 percent, San Simon 7 percent, Magdalena 4 percent, and Swartz 1 percent. Dry and siliceous ores yielded 47 percent of the total silver; zinc and zinc-lead ore 29 percent; copper ore 23 percent; and lead ore, lead-copper ore, and a little silver from placer operations, 1 percent.

Copper.—The output of recovered copper from mines in New Mexico in 1942 was 160,200,000 pounds, a 9-percent increase over the former record annual production in 1941. The Chino open-pit mine of the Kennecott Copper Corporation at Santa Rita, Grant County, continued to be by far the largest producer in the State. The capacity of the concentrator at Hurley is 18,000 tons at the desired grind and optimum metallurgy; however, the daily average quantity treated in 1942 was 20,363 tons. Copper concentrates are treated in the reverberatory furnace and converters at the company smelter at Hurley. Beginning in May 1942, part of the product was fire-refined at Hurley to 99.92-percent purity, and part continued to be cast into blister-copper anodes (99.46-percent purity) for electrolytic refining at Baltimore, Md. Other substantial copper producers in 1942 were the Burro Mountain group of the Phelps Dodge Corporation at Tyrone, Grant County; the Bonney-Anita group near Lordsburg, Hidalgo County; the Stauber mine near Pastura, Guadalupe County; and the Ground Hog-San Jose group near Hanover, Grant County. Copper ore and mine-water precipitates yielded 99 percent of the total copper; virtually all the remainder was recovered from concentrates produced by milling zinc and zinc-lead ores.

Lead.—Most of the lead produced from New Mexico mines in 1942 came from the American Smelting & Refining Co. Ground Hog mine and Hanover mill units in the Central district, Grant County. The total State output of lead was 9,216,000 pounds in 1942, compared with 9,336,000 pounds in 1941. Zinc and zinc-lead ore yielded 93 percent of the total lead, lead and lead-copper ore 4 percent, copper ore 2 percent, and dry and siliceous ore 1 percent.

Zinc.—The output of recoverable zinc from mines in New Mexico increased 23 percent in quantity in 1942 over 1941. A substantial gain in production in the Central district, Grant County, was largely responsible for the increase. The principal producers in 1942 were the Peru Mining Co. (Pewabic and Copper Flat mines), Empire Zinc Co. (Hanover mine group), and American Smelting & Refining Co. (Ground Hog Unit), all in the Central district, Grant County; and the Ozark Smelting & Mining Co. (Waldo mine) and the Empire Zinc Co. (Kelly group), both in the Magdalena district, Socorro County. Other major zinc-producing districts were the Swartz and Pinos Altos, in Grant County; Organ, in Dona Ana County; and Lordsburg and San Simon in Hidalgo County.

Zinc concentrates produced in 1942 amounted to 99,722 tons containing, as shipped, 263 ounces of gold, 48,924 ounces of silver, 569,373 pounds of copper, 1,214,821 pounds of lead, and 107,419,144 pounds of zinc. The average zinc content was therefore 53.86 percent. The zinc and zinc-lead ores (1,049 tons) from New Mexico shipped crude

Digitized by Google

to the Ozark pigment plant at Coffeyville, Kans., averaged 19.28 percent zinc and 9.85 percent lead.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in New Mexico in 1942, by counties, in terms of recovered metals

MINING INDUSTRY

The production of ore from New Mexico mines producing gold, silver, copper, lead, and zinc totaled 8,221,512 tons in 1942, the largest in any year on record and 691,286 tons more than in 1941. Most of the output in 1942, as in 1941, was copper ore mined with power shovels from the Chino open-pit mine at Santa Rita, Grant County. The quantity of each type of ore produced, with its content in terms of recovered metals, is shown in the table that follows. Operating details at both lode and placer mines are given in the following review by counties and districts.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in New Mexico in 1942, with content in terms of recovered metals

Source	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Dry and siliceous gold ore	5,718	1,155	4,378	24,828	85,713	
Dry and siliceous gold-silver ore	29,997	4,112	267,298	8,338	8,193	
Dry and siliceous silver ore	2,116	114	43,459			
	37,831	5,381	315,135	33,166	93,906	
Copper ore	7,631,752	4,815	156,613	[1] 159,037,787	233,207	
Lead ore	694	145	3,653	4,769	208,896	
Lead-copper ore	618	4	3,565	42,303	133,420	
Zinc ore	330,239	238	144,792	965,684	5,991,036	59,813,725
Zinc-lead ore	220,378	131	52,277	116,291	2,554,935	33,108,275
	8,183,681	5,333	360,900	[1] 160,166,834	9,122,094	92,922,000
Total, lode mines	8,221,512	10,714	676,035	[1] 160,200,000	9,216,000	92,922,000
Total, placers		1,247	135			
	8,221,512	11,961	676,170	[1] 160,200,000	9,216,000	92,922,000
Total, 1941	7,530,226	27,845	1,328,317	[2] 146,956,000	9,336,000	75,724,000

[1] Includes 26,042,745 pounds of copper recovered from precipitates from mine water and leached dumps.
[2] Includes 16,818,294 pounds of copper recovered from precipitates from mine water and leached dumps.

METALLURGIC INDUSTRY

The following eight flotation mills treated 98.62 percent of the total New Mexico output of ore in 1942: Chino at Hurley, Empire Zinc at Hanover, Banner at Lordsburg, Peru near Deming, Hanover Unit near Hanover, Waldo near Magdalena, Calumet near Pinos Altos, and Southwestern near Duncan, Ariz. (operated on ore from the Carlisle group at Steeple Rock, N. Mex.). Ore shipped crude to smelters comprised 1.03 percent of the State total; and ore treated by the Little Fanney cyanidation mill at Mogollon, the East Camp cyanidation mill at Steeple Rock, and several small concentration and amalgamation mills scattered throughout the State constituted only 0.35 percent of the total. The Chino reverberatory copper smelter of the Kennecott Copper Corporation at Hurley was operated throughout 1942 on company copper concentrates, siliceous carbonate copper ore, and copper precipitates recovered by leaching of waste dumps. A substantial part of the copper production was marketed for the first time in fire-refined form. The production of copper in this form has tremendously shortened the time of refinement when compared with the time interval of shipment to Baltimore for the refining of blister copper by the electrolytic process. The gold and silver contained in the charge to the fire-refining furnace is not recovered in the operation, as would be the case in electrolytic refining. By sacrificing the gold and silver and shipping marketable refined copper direct to war material-fabricating plants (closer to New Mexico by railroad than Baltimore) much time is saved. The destination and treatment of concentrates and ore produced by other operators in the State and shipped to smelters in other States are discussed in the following review by counties and districts. About 155,400 cubic yards of gravel were treated at three placer mines using dry-land dredges, and a quantity of gravel for which figures are not obtainable was handled at small placers worked by hand methods.

Mine production of metals in New Mexico in 1942, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore amalgamated	500	170	42			
Ore cyanided [1]	28,802	3,195	226,787			
Concentrates smelted	337,736	5,652	341,552	[2]157,754,551	8,614,813	92,594,946
Ore smelted	84,352	1,697	107,654	2,445,449	601,187	327,054
Placer		1,247	135			
		11,961	676,170	160,200,000	9,216,000	92,922,000
Total, 1941		27,845	1,328,317	146,956,000	9,336,000	75,724,000

[1] Cyanide used was approximately 151,013 pounds of Aero Brand calcium cyanide (approximately 48 to 49 percent NaCN).
[2] Includes 26,042,745 pounds of copper recovered from smelting of precipitates from mine water and leached dumps.

CATRON COUNTY

Mogollon district.—The Black Hawk Consolidated Mines Co. operated the Consolidated group and the Little Fanney 200-ton cyanide mill near Mogollon, both under lease from the Lehigh Metals Co. Operations were continuous in 1942 until June 18, at which time the Black Hawk Consolidated Mines Co. relinquished its lease on the property and disposed of all mining equipment but did not remove the mill or its equipment. In addition to ore from the Consolidated group, the mill treated custom ore from the Maude S, Champion, Little Fanney, Deep Down, and Bearup claims. Company and custom ore treated in 1942 totaled 22,256 tons, from which 2,675 fine ounces of gold and 184,888 fine ounces of silver were recovered in cyanide precipitates and refined into bullion, which was shipped to the Denver Mint. Part of the ore produced from the Bearup and Deep Down properties was shipped crude to the El Paso smelter and Ira L. Wright (ore buyer) at Silver City.

COLFAX COUNTY

Mount Baldy district (*Baldy, Elizabethtown, Eagle Nest*).—Only one lode mine and one placer mine in the Mount Baldy district produced in 1942. Fullroe, Inc., worked the Grouse Gulch placer from April 1 until October 15, using a 1¼-cubic yard dragline and portable screening and sluicing plant; this operation yielded most of the gold and silver produced in the district in 1942. The 50-ton cyanide plant at the Moreno-Red Bandana group, 2 miles northeast of Elizabethtown, was operated on a small scale from May 16 until November 16 by Merco, Inc. Mill feed consisted of a small tonnage of crude ore mixed with old tailings. Cyanide precipitates were shipped to the Arkansas Valley smelter at Leadville, Colo. A dragline and other equipment were installed, and a permanent sluice and jig plant was built, with accompanying water-pipe installation, during 1942 on Willow Creek near Therma, for treatment of placer gold-tungsten deposits.

DONA ANA COUNTY

Organ district.—The quantity of ore mined and sold from the Organ district increased from 47 tons in 1941 to 880 tons in 1942. Small-scale operations at the Big Buck property produced 42 tons of crude ore, which was treated in the Hanover custom mill of the American Smelting & Refining Co. Operations at the Merrimak mine, largest producing property in the district, began in July 1942, and thereafter regular shipments of zinc-copper-lead-silver ore averaging 15 percent zinc were made to the American Smelting & Refining Co. selective-flotation zinc-lead custom mill at Hanover, Grant County. Five tons of zinc ore from the Pagoda mine also were treated in the Hanover custom mill.

GRANT COUNTY

Burro Mountain district (*Tyrone*).—Throughout 1942 the Phelps Dodge Corporation continued leaching the old mine workings *in situ*, by percolating water and precipitating copper from the resulting copper-bearing water, at its Burro Mountain mine, 13 miles southwest of Silver City. During the year the capacity of the precipitation plant

Digitized by Google

was increased, and additional pumping facilities were installed. L. Yacomo and Marvin Fuller unwatered the Full Moon mine in March and began shipping zinc-lead ore to the custom mill at Hanover; small but continuous production was maintained at the property for the remainder of the year. A lessee on the Copper Sulphite claim shipped 123 tons of zinc-lead-silver ore to the Hanover custom mill for treatment. The Burro Mountain Leasing Co. worked the Thompson group of claims, beginning in August, and shipped 87 tons of oxidized copper ore to the El Paso smelter. A small-scale sluicing operation on the Paymaster placer recovered gold which was shipped to the Denver Mint.

Central district (*Bayard, Fierro, Georgetown, Hanover, Santa Rita*).—The Kennecott Copper Corporation Chino Mines Division, largest producer of copper in New Mexico, operated its open-pit mine at Santa Rita and flotation mill and reverberatory copper smelter at Hurley at over capacity throughout 1942. The output of copper was the largest in the history of the operation. Considerable copper was also recovered from leaching operations and from siliceous carbonate copper ore used in the converters as a flux. Additional grinding equipment was installed in the 20,000-ton concentration mill, making it possible for the mill to operate at over optimum metallurgical capacity throughout the year. Molybdenum, gold, and silver are recovered in the mill as byproducts. A substantial part of the copper was marketed for the first time in fire-refined form. Installation of a 230-foot-diameter Dorr thickening tank and a new lime-burning plant was completed, and they were put into operation early in 1942. Although drought conditions prevailed throughout the year, enough water for plant requirements was obtained through drilling additional wells and from water reclaimed from the Dorr-thickener installation.

Zinc production in the Central district in 1942 was the greatest in the history of the district. In spite of difficulties caused by governmental priorities, critical labor shortages, and marked absenteeism, which prevented maximum production, the output of recovered zinc increased 22.30 percent over 1941. Production of recovered lead, however, decreased 17.86 percent from 1941. The Peru Mining Co. expanded operations at its Copper Flat and Pewabic mines and shipped by railroad nearly 50 percent greater tonnage of ore to the company 500-ton flotation mill at Deming. Besides ore from the company properties in the Central district, the mill treated custom ore from two zinc properties in Arizona. Concentrates produced were shipped to the zinc retort plant at Dumas, Tex. Late in 1942 the company began development and search for ore in the Kearny property, which resulted favorably, and output of zinc ore began in March 1943. The Empire Zinc Co. operated its Hanover mine group and selective-flotation mill continuously in 1942 with an output virtually the same as that maintained in 1941. Maintenance of full capacity of the mill was assured only by shipment of additional ore from the company Lynchburg mine at Kelly, Socorro County. Such shipments and treatment represented a money loss. Most of the zinc concentrates produced were shipped to the New Jersey Zinc Co. plant at Depue, Ill. (Mineral Point Zinc Division); byproduct lead concentrates made were shipped to the El Paso smelter. Production of zinc concentrates from the Hanover milling unit (formerly Combination-Black Hawk mill), operated under lease by the American

Digitized by Google

Smelting & Refining Co., was nearly two-thirds greater than in 1941. Most of the ore treated came from the company Ground Hog-San Jose group, which produced in addition to zinc-lead-copper-silver milling ore a small tonnage of lead-copper-silver-gold ore, which was shipped crude to the El Paso smelter. About 22 percent of the total ore milled was custom ore from the Combination, Hobo, Free Gold, Barringer, and Peerless properties in the Central district; the Columbia, Grandview, and Royal John claims in the Swartz (Carpenter) district; the Manhattan and Baldback mines in the Pinos Altos district; the Copper Sulphite and Full Moon properties in the Burro Mountain (Tyrone) district; the Big Buck, Merrimak, and Pagoda mines near Organ; the Ruth mine near Lordsburg; the Silver Hill property near Steins; the Percha mine near Kingston; and the Nitt and El Tigre properties near Magdalena. Several small shipments of crude ore were made to the El Paso smelter from the Little Goat and the Georgetown Extension group at Hanover.

Late in 1941 the United States Smelting, Refining & Mining Co. began acquiring, under lease and option, a number of claims in the vicinity of Vanadium, which it later consolidated into what is now known as the Bullfrog mine. Development and exploration at this mine were carried on throughout the year and consisted of a new 626-foot shaft, 2,938 feet of drifts, 23,618 feet of diamond-drill holes, construction of a steel headframe, shops, office, and warehouse. In July 1942 a contract was let for the construction of a 250-ton selective-flotation mill adjacent to the mine. Difficulty in obtaining equipment and carpenters retarded the normal construction progress, so that the mill was not completed and put into operation until March 1943. Mill feed for the first few months of operation consisted of ore (from development and exploration) that had been stock-piled at the mine. It is expected that this operation will add materially to the production of zinc in the Central district.

Ground sluicing of dry-wash gravels in Gold Gulch by prospectors and vacationists recovered a little placer gold.

Eureka district.—Intermittent small-scale operations at the Hornet and Bonanza properties produced small lots of lead ore, which were shipped crude to the El Paso smelter or sold to Ira L. Wright, ore sampler and purchaser, at Silver City.

Pinos Altos district.—A lessee operating intermittently the 20-ton Calumet mill 1 mile south of Pinos Altos treated zinc-lead-bearing tailings reported from the Cleveland dump and shipped zinc and lead concentrates to the Amarillo and El Paso smelters. Lessees on the Baldback and Manhattan mines shipped crude zinc-lead-copper-gold-silver ore to the Hanover custom mill. Gold-silver-copper-lead and gold-silver-copper ores were shipped in small lots to the El Paso smelter and Ira L. Wright from the Blue Jay, Buckhorn, and Langston prospects in the Pinos Altos district. Virtually all the placer gold from the district in 1942 was recovered by Cooperative Placers, which operated a dragline land dredge in Santo Domingo Gulch until April. Numerous small placers, usually operated after flash showers and cloudbursts that reworked the gulch gravels, were continued throughout the year by residents of the community.

Red Rock district.—Three tons of copper-silver ore were shipped in 1942 from the Fence claim in the Red Rock district.

Digitized by Google

Steeple Rock district.—The Southwestern Mineral Co. worked the Center claim and Carlisle dump in 1942 from January 1 until June 30 and produced 3,459 tons of gold-silver-copper-lead ore, of which 3,130 tons were concentrated in the company 100-ton flotation mill at Duncan, Ariz., and 329 tons were shipped crude to the El Paso smelter. Plans were being made early in 1943 to reopen the property for the production of zinc and lead. Reserves are estimated at 100,000 tons of 5-percent zinc, 2-percent lead, and 4½-percent copper. The Exploration Syndicate, Inc., continued to operate the East Camp group until April 1942. All the ore produced was treated in the company 75-ton cyanide mill at the mine; the gold-silver bullion recovered was shipped to the Denver Mint. Flotation cells were added to the mill late in 1942, and the company plans to produce zinc concentrates from East Camp ore in 1943. Small shipments of crude ore were made to the International Smelting & Refining Co. smelter at Miami, Ariz., from the Laura, Norman King, and Ontario properties.

Swartz (or Carpenter or Camp Monarch) district.—The Black Range Development Co. reopened the Grandview and Columbia properties in February 1942 and produced 6,893 tons of zinc-lead-silver ore, which was trucked to the Hanover custom mill. A. L. Owen shipped zinc-lead-silver ore regularly from the Royal John mine to the Hanover custom mill.

White Signal district.—A shipment of 128 tons of crude smelting ore reported to be from the True Blue claim was made in 1942. Other activities in the White Signal district consisted of two one-man operations that produced small lots of crude ore which were sold to Ira L. Wright at Silver City. Production came from the Big Chief and Combination prospects.

GUADALUPE COUNTY

The Stauber mine near Pastura was operated under lease in 1942 from January to June 31 by Alex Bonnyman, Jr., and the remainder of the year by the Guadalupe Mining Co. Shipments to the El Paso smelter for the year amounted to 7,498 tons of siliceous copper ore averaging 4.24 percent copper and 0.105 ounce of silver to the ton.

HIDALGO COUNTY

Apache district.—A lessee operating the Apache group shipped 1 carload of zinc smelting ore averaging 30 percent zinc to the Ozark Smelting & Mining Co. leaded-zinc pigment plant at Coffeyville, Kans.

Lordsburg district.—The Banner Mining Co., second-largest producer of copper in New Mexico, operated the Bonney and Anita No. 1 mines and a 500-ton flotation mill, 6 miles south of Lordsburg, continuously throughout 1942. Ore produced from the various levels of the mine is hoisted through a 1,475-foot, vertical, three-compartment main shaft situated 100 feet from the mill. Copper-gold-silver concentrates were sold to the El Paso smelter. Production from the old Anita mine, 5 miles south of Lordsburg, was started early in 1942 following an intensive rehabilitation and development program, which consisted in unwatering the mine, reconditioning the 800-foot shaft, diamond drilling 297 feet of exploratory drill holes, and driving 130

Digitized by Google

feet of raise and 43 feet of winze. The ore was trucked to the Banner mill at the Bonney mine for treatment. Development at the Bonney mine consisted of 2,744 feet of exploratory diamond drilling, sinking 126 feet of shaft, and driving 2,607 feet of drift. The National Zinc Corporation obtained a lease on the Ruth property and began shipping crude zinc-lead sulfide ore on April 4 to the Hanover custom mill (Grant County). Operations were continued throughout the year. Exploration and development comprised sinking 165 feet of shaft and driving 585 feet of drift. In 1943 an experimental 50-ton gravity-concentration pilot plant was installed on the Ruth property. If the metallurgical results of the pilot plant are satisfactory, the National Zinc Corporation plans to construct a larger mill for treating the Ruth ore.

The Federal Bureau of Mines late in 1942 and early in 1943 explored by diamond drilling at the Atwood group of claims on Atwood Hill near Valedon, 4 miles south of Lordsburg, in addition to rehabilitating the Henry Clay shaft on the property. If Bureau findings are satisfactory, active mining probably will be done on this property in 1943.

San Simon (Steins) district.—The Byrd Mining Co. operated, under lease, the Silver Hill property 9 miles south of Steins and began regular carload shipments of zinc-lead sulfide ore to the Hanover custom mill (Grant County) in May. Ore shipped averaged 8.14 percent lead, 3.26 percent zinc, and 1.86 ounces of silver to the ton. The Shattuck-Denn Mining Co. acquired the McGhee mine under a long-term lease late in November and began renovating equipment and buildings preparatory to production of ore. It is planned to treat the ore in the Shattuck-Denn custom mill at Bisbee, Ariz. The Diamond Mining Co. operated the Volcano group, 6 miles north of Steins, from April 1 to November 1 and shipped 2,115 tons of dry silver ore to the Miami (Ariz.) smelter. Small lots of crude smelting ore were shipped from the Carbon Hill and Central mines.

LINCOLN COUNTY

Jicarilla district.—All the output from the Jicarilla district and Lincoln County in 1942 was in small lots of placer gold recovered from stream gravels in the Jicarilla Mountains southeast of Ancho. The gold produced was sold to merchants in Ancho and Jicarilla.

LUNA COUNTY

Cooks Peak district.—Small tonnages of lead-silver ore were shipped through Ira L. Wright at Silver City in 1942 from the "85"-Ethel group, Lookout, Mickey, Surprise, and Mahoney Shaft No. 1 properties.

Deming district.—The Peru Mining Co. operated continuously in 1942, at slightly over capacity, its 500-ton selective-flotation mill at Wemple, near Deming. Most of the ore treated was moved by railroad from the company-operated Pewabic and Copper Flat mines in the Central district (Grant County). Some custom ore from two zinc properties in Arizona also was treated. The output of zinc concentrates increased nearly 50 percent over 1941.

Digitized by Google

OTERO COUNTY

Sacramento district.—I. W. Morrison shipped 41 tons of lead-copper-silver ore to the El Paso smelter from the Warwick claim in 1942.

SANTA FE COUNTY

Ortiz Mountains (Cerrillos) district.—Development and exploration on the Mina de Tira property 2½ miles north of Cerrillos produced 22 tons of lead-silver-copper-gold ore, which was shipped to the El Paso smelter. The Cerrillos Lead & Zinc Co. operated under lease the Pennsylvania mine, 12 miles northwest of Cerrillos, during the last 3 months of 1942 and shipped 43 tons of zinc-lead-silver ore to the Hanover custom mill (Grant County). Sluicing stream gravels on the Ortiz Grant southeast of Cerrillos recovered small lots of placer gold.

San Pedro or New Placers district.—A lessee worked the Candelari mine on a small scale and trucked the ore produced 4 miles to his 10-ton amalgamation mill at Golden for treatment. At the Old Timer mine, near Golden, 100 tons of ore were mined and treated in a Huntington mill. Several individuals continued to sluice placer gravels in the vicinity of Golden.

SIERRA COUNTY

Chloride (Apache, Cuchillo Negro) district.—The only producing properties in the Chloride district in 1942 were the Apache group and the Minnehaha claim, from which small lots of smelting ore were shipped direct to the El Paso smelter or through Ira L. Wright at Silver City.

Hermosa district.—The only output from the Hermosa district in 1942 was 6 tons of lead-silver ore from the Pelican group.

Kingston district.—A lessee on the Percha mine in the Black Range west of Kingston operated part of 1942 and shipped 99 tons of zinc-lead-copper-silver ore to the Hanover custom mill in Grant County for treatment.

Las Animas district (Hillsboro).—Intermittent small-scale operations on the Tresness, Nicolds, and Wicks claims in the Las Animas district produced several lots of smelting ore, which were shipped to the El Paso smelter or to Ira L. Wright at Silver City.

The John I. Hallett Construction Co. continued operations in 1942 until November 15 at the leased Gold Dust, Graf Von Luxemburg, Bunker Hill, and other placers in a group about 8 miles east of Hillsboro. The equipment consists of two gasoline-powered dragline excavators of 1- and 1¼-cubic yard capacity, a Coulter-Ainlay bowl recovery plant mounted on wheels, water-storage tanks, and pumps. Sluicing and panning at other placers in the Las Animas district recovered small lots of gold.

Pittsburg and Caballos Mountains district.—Itinerant prospectors panned for gold in 1942 on the stream gravels of the Pittsburg and Caballos Mountains district and sold what gold they recovered to the Myers Co. store at Hatch.

Tierra Blanca district.—L. E. Cleveland shipped 1 ton of lead-silver smelting ore from his Silver Bell claim through Ira L. Wright, ore buyer, at Silver City.

Digitized by Google

SOCORRO COUNTY

Magdalena district.—Production of recoverable zinc from the Magdalena district increased from 5,159,000 pounds in 1941 to 6,370,000 pounds in 1942, or 23.47 percent; the output of recovered lead increased from 847,400 to 1,728,000 pounds, or 103.92 percent. Raskob Mining Interests, Inc., continued to operate, under lease and option, the Waldo mine and 200-ton flotation mill until July 1, when it relinquished the lease and the property reverted to the owners, the Sherwin-Williams Co. The property remained idle until October 1942, when the Ozark Smelting & Mining Co., (subsidiary of the Sherwin-Williams Co.) resumed production and continued to operate the mine and mill the remainder of the year. Ore milled during 1942 by both operators totaled 29,118 tons, yielding 4,012 tons of zinc concentrates and 291 tons of lead concentrates. The ore milled contained traces of gold, silver, and copper and averaged 2.8 percent lead and 12.7 percent zinc. The concentrates produced were shipped to the Ozark Smelting & Mining Co. pigment plant at Coffeyville, Kans., the El Paso smelter, and the Dumas smelter of the American Zinc Co. of Illinois. On April 10, 1943, the Waldo property (mine and mill) was purchased by the American Smelting & Refining Co., which continued operations. The Kelly Unit (Lynchburg and Kelly mines) of the Empire Zinc Co. was worked by lessees, who shipped zinc-lead ore to the Empire Zinc Co. flotation mill at Hanover and to the Ozark Smelting & Mining Co. pigment plant at Coffeyville, Kans. Victor Papa shipped 267 tons of lead-copper-silver-gold ore from the West Star property to the El Paso smelter. J. A. McDonald began operations on the Nitt claim in August and shipped crude zinc-lead-silver ore to the Hanover custom mill (Grant County) in addition to making several shipments of copper-silver ore to the El Paso smelter. A lessee on the El Tigre mine shipped 1 carload of zinc-lead ore to the Hanover custom mill.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN OREGON

(MINE REPORT)

By CHARLES WHITE MERRILL AND H. M. GAYLORD

SUMMARY OUTLINE

	Page		Page
Summary	457	Mining industry—Continued.	
Calculation of value of metal production	458	Ore classification	462
Mine production by counties	460	Metallurgic industry	461
Mining industry	461	Review by counties and districts	465

SUMMARY

The gold-mining industry of Oregon collapsed during 1942. In 1940 gold production reached an all-time high, but by the end of 1942 the few mines with substantial gold output in the earlier months of the year had suspended operations. Silver and lead production also decreased in both quantity and value, and the small rise in copper output was not significant in the State total for the four metals.

The total value of the gold, silver, copper, and lead (in terms of recovered metals) produced in Oregon was $1,708,297 in 1942 compared with $3,602,468 in 1941. It was divided among the metals as follows: Gold, 95 percent; silver, 4 percent; and copper and lead combined, 1 percent. No recovery of zinc has been reported since 1937. Baker County continued to be the leading metal producer and contributed 40 percent of the State total value; Grant County yielded 27 percent, Jackson County 18 percent, Josephine County 7 percent, and the other eight producing counties 8 percent. Distribution of production, by counties, was much the same as in 1941.

Rising wages, enlistment of miners in the armed forces, migration of miners to war industries, rising costs of supplies and equipment and the difficulties of obtaining them, higher taxes, and a fixed price for gold and silver (principal metals produced in the State) were factors that continued to crush the industry in 1942 as in 1941. When the War Production Board issued Order L–208 October 8, production, which had already sunk to approximately one-third of its 1940 level, quickly collapsed. The five leading gold producers for the year 1942 suspended operations between October 7 and 31; they supplied 50 percent of the State output.

Lode mines were affected sooner than placers, so that only 17 percent of the total gold in 1942 came from lodes. For a number of years lode mines had produced about one-third and placers two-thirds of the gold output.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

Yardage figures used in measuring material treated in placer

operations are bank measure; that is, the material is measured in the ground before treatment.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1938–42

Year	Gold [1]	Silver [2]	Copper [3]	Lead [4]	Zinc [4]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1938	$35.00	[5] $0.646+	$0.098	$0.046	$0.048
1939	35.00	[6] .678+	.104	.047	.052
1940	35.00	[7] .711+	.113	.050	.063
1941	35.00	[7] .711+	.118	.057	.075
1942	35.00	[7] .711+	.121	.067	.093

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.
[2] Treasury buying price for newly mined silver.
[3] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production but excludes value of foreign copper delivered to Metals Reserve Co. for domestic consumption.
[4] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production.
[5] $0.64646464. [6] $0.67878787. [7] $0.71111111.

Mine production of gold, silver, copper, lead, and zinc in Oregon, 1938–42, and total, 1852–1942, in terms of recovered metals

Year	Mines producing [1]		Ore, old tailings, etc. (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1938	84	157	74,936	81,729	$2,860,515	100,507	$64,974

1941	6	4,600	94	3,290	.715
1942	4	1,500	50	1,750	1.167
Grand total placer:					
1938	157	11,355,000	54,331	1,901,585	.167
1939	201	13,322,000	60,779	2,127,265	.160
1940	[6] 192	16,684,000	71,577	2,505,195	.150
1941	153	14,646,000	60,430	2,115,050	.144
1942	83	8,150,000	38,336	1,341,760	.165

[1] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

[2] Includes all placer operations using dragline excavator for delivering gravel to floating washing plant.

[3] Includes all placer operations using suction pump for delivering gravel to floating washing plant, except those producing less than 100 ounces of gold, which are included under "Small-scale hand methods"; no suction dredges reported for 1938–40, inclusive, and 1942.

[4] Includes all placer operations using power excavator and washing plant, both on dry land; when washing plant is movable, outfit is termed "dry-land dredge."

[5] Includes all operations in which hand labor is principal factor in delivering gravel to sluices, long toms, dip boxes, pans, etc.

[6] A mine using more than 1 method of recovery is counted but once in arriving at total for all methods.

Digitized by Google

Gold.—Production of gold in Oregon in 1942 decreased 52 percent compared with 1941—the output from placers 37 percent and that from lode mines 78 percent. Of the total placer gold, connected-bucket dredges recovered 56 percent, dragline dredges 35 percent, hydraulicking and small-scale hand methods 4 percent each, and nonfloating washing plants (with mechanical excavators) and drift mines 1 percent. Virtually all the lode gold was derived from dry ores and most (96 percent) of it from dry gold ore. Although 131 properties produced in 1942, the bulk of the gold came from relatively few mines; the following 10 properties, listed in order of output, supplied 71 percent of the State total: Sumpter Valley Dredging Co. (connected-bucket dredge), Porter & Co. (connected-bucket dredge), Stearns & Owens (Kubli operation) (dragline dredge), Ferris Mining Co. (dragline dredge), Sunshine Mining Co. (Burnt River Division) (connected-bucket dredge), Timms Gold Dredging Co. (connected-bucket dredge), Ellis Mining Co. (gold ore), Stearns & Owens (Alaska of Oregon operation) (dragline dredge), Western Gold Dredging Co. (connected-bucket dredge), and Consuelo Oregon Mines (dragline dredge). Only one of the 10 is a lode mine.

Silver.—Silver production in Oregon in 1942 decreased 68 percent compared with 1941. Of the State total, Jefferson County yielded almost two-thirds, and most of the remainder came from Lane and Baker Counties; dry silver ore yielded 45 percent, dry gold ore 27 percent, dry gold-silver ore 20 percent, and placer gravels almost all the rest. Smelting of crude ore accounted for 59 percent of the total lode silver and smelting of concentrates for virtually all the rest.

Copper, lead, and zinc.—Most of the copper output of Oregon in 1942 was a byproduct of ores worked primarily for their gold content. The lead output of the State, which totaled only 46,000 pounds, was derived entirely from precious-metal ores. No zinc was reported recovered.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, and lead in Oregon in 1942, by counties, in terms of recovered metals

County	Mines producing [1]		Gold					
			Lode		Placer		Total	
	Lode	Placer	Fine ounces	Value	Fine ounces	Value	Fine ounces	Value
Baker	11	11	2,731	$95,585	16,455	$575,925	19,186	$671,510

Mine production of gold, silver, copper, and lead in Oregon in 1942, by counties, in terms of recovered metals—Continued

County	Silver (lode and placer)[1]		Copper		Lead		Total value
	Fine ounces	Value	Pounds	Value	Pounds	Value	
Baker	10,959	$7,793	6,000	$726			$680,029
Coos	7	5					600
Curry	7	5					985
Douglas	24	17					3,867
Grant	4,936	3,510	4,000	484			460,499
Harney							210
Jackson	1,336	950			2,000	$134	308,279
Josephine	526	374	16,000	1,936			120,610
Malheur	38	27					8,672
Union							35
Other counties[2]	69,543	49,453	180,000	21,780	44,000	2,948	124,511
	87,376	62,134	206,000	24,926	46,000	3,082	1,708,297
Total, 1941	276,158	196,379	166,000	19,588	118,000	6,726	3,602,468

[1] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.
[2] Output from property not classed as a "mine."
[3] Jefferson and Lane Counties.
[4] Sources of total silver as follows—1942: 80,235 ounces from lode mines and 7,141 ounces from placers; 1941: 264,953 ounces from lode mines and 11,205 ounces from placers.

MINING INDUSTRY

Of the 31,728 tons of ore (including 3,075 tons of old tailings) sold or treated in Oregon in 1942, Lane County produced 12,442 tons or 39 percent, Baker County 6,623 tons (including 2,500 tons of old tailings) or 21 percent, Josephine County 4,795 tons or 15 percent, Grant County 4,721 tons or 15 percent, and Jefferson County 2,615 tons (including 400 tons of old tailings) or 8 percent. Almost 92 percent of the ore (including old tailings) was dry gold ore, and virtually all the remainder was dry gold-silver and silver ore.

The six properties worked by connected-bucket dredges had one dredge each, none of which worked at more than one property in 1942; at the end of the year all operations had been suspended. Ten dragline dredges washed gravel at 14 Oregon properties, but none was in operation at the close of the year; the dragline excavators were equipped as follows: 3 each with 2- and 1¼-cubic yard buckets and 1 each with a 3-, 2½-, 1¾-, and 1½-cubic yard bucket.

Reports on the use of quicksilver at Oregon placer mines indicate that 867 pounds were consumed during 1942. The placer operators reporting on quicksilver consumption furnished 1942 data from which the following quantities of gold recovered per pound of quicksilver consumed have been calculated (1941 figures in parentheses): Connected-bucket dredges, 37 ounces of gold per pound of quicksilver (none in 1941); dragline dredges, 76 ounces (55); hydraulic mines, 30 ounces (21); and small-scale hand operations, 27 ounces (6).

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Digitized by Google

Ore and old tailings sold or treated in Oregon in 1942, with content in terms of recovered metals

Source	Material sold or treated		Gold	Silver	Copper	Lead

METALLURGIC INDUSTRY

Of the State total ore and old tailings (31,728 tons), 58 percent was treated in concentrating mills, most of which used flotation; 23 percent was treated in amalgamation and cyanidation mills, with or without concentration equipment; and 19 percent was shipped crude to smelters. Ultimate recovery of 50 percent of the total lode gold was from the smelting of ore; 29 percent from the smelting of concentrates; 16 percent as bullion from cyanidation of ore and old tailings; and 5 percent as bullion from amalgamation of ore. All material requiring smelting was shipped out of the State, as Oregon has no smelters.

Data furnished by operators of some of the gold and silver mills show that 4,003 pounds of 91-percent sodium cyanide were consumed in recovering 1,235 ounces of gold and 198 ounces of silver from 4,213 tons of ore and 2,500 tons of old tailings, and that 21 pounds of quicksilver were used in recovering 170 ounces of gold and 44 ounces of silver from 278 tons of ore.

Mine production of metals in Oregon in 1942, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated	Gold	Silver	Copper	Lead
	Short tons	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*
Ore and old tailings amalgamated	565	437	95	----	----
Ore and old tailings cyanided	6,838	1,246	204	----	----

Total Oregon	48	83	31,728	7,897	38,336	46,233	87,376	206,000	46,000	1,708,297

[1] Only those counties and districts shown separately for which Bureau of Mines is at liberty to publish figures; others producing listed in footnote 10 and their output included under "Combined counties and districts."

[2] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

[3] Source of total silver as follows: 80,235 ounces from lode mines and 7,141 ounces from placers.

[4] Included under "Combined counties and districts."

[5] Exclusive of placer output, which is included under "Combined counties and districts."

[6] Greenhorn district lies in both Baker and Grant Counties.

[7] Mormon Basin district lies in both Baker and Malheur Counties.

[8] Output from a property not classed as a "mine."

[9] Greenback district lies in both Jackson and Josephine Counties.

[10] Includes following districts: Baker (placer) in Baker County; Granite (placer) in Grant County; Elk Creek and Greenback in Jackson County; Ashwood in Jefferson County; and Bohemia in Lane County.

Digitized by Google

BAKER COUNTY

Baker district.—The Midas mine in the Pocahontas section of the Baker district was worked by drifting and hydraulicking during 1942. The Alec Johnson mine shipped gold ore to a smelter.

Cracker Creek district.—The Argonaut mine shipped gold ore to a smelter during 1942. The Bald Mountain mine was worked by lessees; 2 tons of high-grade ore treated by amalgamation yielded 7 ounces of gold and 5 ounces of silver, and 26 tons of gold ore shipped to a smelter contained 14 ounces of gold and 144 ounces of silver. The Ellis Mining Co. remodeled the E & E mill in 1942; the company holdings, which include the Eureka & Excelsior, Tabor Fraction, and Columbia mines, were operated by lessees, who shipped to a smelter 3,472 tons of ore containing 2,156 ounces of gold, 5,980 ounces of silver, and 6,196 pounds of copper.

Greenhorn district.—The Sunshine Mining Co. (Burnt River Division) operated a connected-bucket dredge in 1942 until War Production Board Order L–208 resulted in suspension of operations in October. The Oroplata Mining Co. operated a dragline dredge near Whitney from January 25 until March 11, when operations were suspended for the duration of the war; the dragline excavator was equipped with a 2½-cubic yard bucket.

Mormon Basin district.—G. W. Cartwright hydraulicked at the Rye Valley placers during 1942. J. W. Frisco worked the Webber mine by hydraulicking from June 1 until September 30 and recovered 19 ounces of gold and 14 ounces of silver.

Sparta district.—Lessees worked the Macy mine from January 1 to February 21, 1942, when the lease was terminated; 60 tons of ore treated by amalgamation yielded bullion, containing 11 ounces of gold and 4 ounces of silver, and 1 ton of gravity concentrate, containing 2 ounces of gold and 1 ounce of silver.

Sumpter district.—The Sumpter Valley Dredging Co., largest producer of gold in Oregon in 1942, washed 2,704,734 cubic yards of gravel and recovered 10,259 ounces of gold and 2,360 ounces of silver; the dredge (Yuba type) had seventy-two 9-cubic foot buckets. Operations were suspended October 31 because of War Production Board Order L–208. Consuelo Oregon Mines operated a dragline dredge during the first 6 months, and the Northwest Development Co. operated a dragline dredge on Powder River during the first 7 months of the year.

Upper Burnt River district.—G. W. Elliott worked the Elliott drift mine from January 1 to August 1, 1942; 800 cubic yards of gravel yielded 25 ounces of gold and 4 ounces of silver.

Virtue district.—K. Grabner operated the Cliff mine from January 1 to July 1, 1942; 100 tons of ore treated by amalgamation yielded 32 ounces of gold and 5 ounces of silver; 48 tons of gold ore shipped to a smelter contained 42 ounces of gold and 7 ounces of silver. Old tailings at the Gold Center mine were treated by cyanide leaching between June 1 and October 1.

Weatherby district.—Lovejoy Mines, in the Chicken Creek section of the Weatherby district, produced a small quantity of gold by amalgamation in 1942.

GRANT COUNTY

Canyon district.—Hydraulicking at the Quartz Gulch mine from February 15 to July 5, 1942, resulted in the recovery of 20 ounces of

Digitized by Google

gold and 4 ounces of silver from 8,000 cubic yards of gravel. Hydraulicking was carried on at the Tracy mine from March 5 to May 5. The Ferris Mining Co. operated a dragline dredge from January 1 until operations were suspended October 26; the dragline excavator was equipped with a 3-cubic yard bucket. The Western Gold Dredging Co. operated a connected-bucket dredge on John Day River from January 1 to October 13; the dredge had seventy-two 6-cubic foot buckets.

Granite district.—Porter & Co. operated a connected-bucket dredge with sixty-two 4½-cubic foot buckets on Granite, Clear, Olive, and Crane Creeks from January 1 until October 16, 1942. Bruce Dennis operated the Constitution mine; gold ore was treated by flotation, and gold concentrates were shipped to a smelter. The Cougar-Independence Mining Co. shipped gold ore and gold concentrates from the Cougar Independence mine; operations were suspended when repair parts for the company mill became unobtainable.

Greenhorn district.—The Timms Gold Dredging Co. during 1942 operated a connected-bucket dredge on the DeWitt ranch situated in that part of the Greenhorn district extending into Grant County from Baker County. Klein & Manley amalgamated 16 tons of ore from the Golden Gate mine and recovered 30 ounces of gold and 5 ounces of silver. W. Gardner shipped gold ore from the Morning mine to a smelter. James & Hay carried on development work at the Rabbit mine from January 1 to December 1; gold ore was treated by amalgamation.

North Fork John Day district.—A gold shipment was made from the North Fork placer in 1942 as a result of the final clean-up of the dragline dredge which had suspended operations in 1941.

JACKSON COUNTY

Elk Creek district.—A small quantity of lead concentrates resulted from test work carried on during 1942 by Al Sarena Mines, Inc., at the Al Sarena mine in the Buzzard section of the Elk Creek district; the concentrates were shipped to a smelter.

Gold Hill district.—Stearns & Owens operated a dragline dredge on the Kubli ranch from January 1 until October 7, 1942; the dragline excavator was equipped with a 2-cubic yard bucket. Lance Bros. hydraulicked 1,000 cubic yards of gravel between January 1 and April 1, recovering 20 ounces of gold and 3 ounces of silver. The Pleasant Creek Mining Corporation operated a connected-bucket dredge on Pleasant Creek from January 1 to June 1; the dredge was equipped with fifty-six 3-cubic foot buckets. H. H. McClung recovered 16 ounces of gold and 3 ounces of silver by hydraulicking on Wards Creek. Sandry & Whipple operated the Gold Chloride mine from January 1 to June 20; 38 ounces of gold and 9 ounces of silver were recovered from 36 tons of ore. J. T. Breeding worked the Lucky Bart group during the year.

Greenback district.—H. B. Warner shipped high-grade gold ore from intermittent operations at the Warner mine to a smelter during 1942.

Jacksonville district.—The Jackson Mining Co. operated a nonfloating washing plant, to which gravel was delivered by mechanical means, on the George Wendt ranch from January 1 until March 1, 1942. The C. & D. Mining Co. operated a dragline dredge with a dragline excavator, having a 1¼-cubic yard bucket, from January 1 to April 25;

Digitized by Google

20,000 cubic yards of gravel yielded 170 ounces of gold and 27 ounces of silver.

Upper Applegate district.—Stearns & Owens operated a dragline dredge on the Alaska of Oregon and B–H properties during 1942. The B–H Co. operated a dragline dredge with a dragline excavator, having a 1½-cubic yard bucket, from January 1 to May 7; 177,500 cubic yards of gravel yielded 843 ounces of gold and 131 ounces of silver. F. L. Smith carried on intermittent hydraulicking on the Federal mine throughout the year. The Crescent Pacific Mining Co. operated a dragline dredge with a dragline excavator equipped with a 1¾-cubic yard bucket from January 1 to 28, and 45,850 cubic yards of gravel yielded 174 ounces of gold and 22 ounces of silver; a caterpillar and carry-all was used for resoiling the dredge area. The Southern Oregon Mining Co., Ltd., operated a dragline dredge on the McDonough and the Smith-McDonough ranches from January 1 to May 5; the dragline excavator was equipped with a 1¼-cubic yard bucket. Hydraulicking was carried on at the Sterling property during the season.

JEFFERSON COUNTY

Ashwood district.—Oregon King Mines, Inc., operated the Oregon King mine from January until October 1942, when work was continued by Fenton & Silbaugh under the name of Oregon King Mines; 1,180 tons of gold-silver ore and 400 tons of old tailings were treated in the company 50-ton flotation mill; 261 tons of resulting gold-silver concentrates and 1,035 tons of silver ore were shipped to a smelter. The concentrates contained 131 ounces of gold, 17,338 ounces of silver, 5,815 pounds of copper, 14,185 pounds of lead, and 18,103 pounds of zinc; the ore shipped direct to the smelter contained 202 ounces of gold, 39,459 ounces of silver, 9,742 pounds of copper, 17,566 pounds of lead, and 37,351 pounds of zinc.

JOSEPHINE COUNTY[1]

Galice district.—S. Alderson carried on hydraulicking operations at the Klum mine from February 2 to April 13, 1942. Young & Vandeventer hydraulicked at the Lewis mine. The Lewis Investment Co. operated the Benton mine from January 1 to April 8, when work was suspended because of rising costs of supplies and shortage of labor; gold ore was treated in the company 60-ton countercurrent cyanidation plant. Gold ore was shipped from the Almeda mine.

Grants Pass district.—R. Heller operated the Sunset mine on Jump-off Joe Creek during 1942; 4,000 cubic yards of gravel yielded 17 ounces of gold and 2 ounces of silver. The Yewwood mine was also worked by hydraulicking.

Greenback district.—Hydraulicking was carried on at the Blue Channel mine from January 1 to May 1, 1942. The Little Artie mine was worked. Gold was produced by hydraulicking at the Goff mine during the year.

Illinois River district.—Laguna Mines hydraulicked during 1942. N. W. Cole worked the Eureka mine from January 1 to August 1.

Waldo district.—Hydraulicking at the Esterly mine in 1942 yielded 373 ounces of gold and 21 ounces of silver from the washing of 63,700

[1] *See also* State of Oregon Department of Geology and Mineral Industries, Oregon Metal Mines Handbook: Bull. 14-C, 1942, 229 pp.

Digitized by Google

cubic yards of gravel. A small shipment of copper ore from the Cow Boy mine was sent to a smelter.

LANE COUNTY

Bohemia district.—H. & H. Mines completed construction of a mill and power plant at the Champion mine in 1942; gold ore was treated in a 100-ton flotation plant, and copper and lead concentrates were shipped to a smelter. High cost of materials and shortage of labor caused suspension of operations in August.

MALHEUR COUNTY

Mormon Basin district.—Whitney & Boydstun operated a non-floating washing plant, to which gravel was delivered by a carry-all, from March 10 to July 10, 1942; 16,000 cubic yards of gravel yielded 240 ounces of gold and 38 ounces of silver.

OTHER COUNTIES

Small outputs in 1942 were reported from Coos, Curry, Douglas, Harney, and Union Counties.

Details of production by counties and districts are given in the preceding table.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN SOUTH DAKOTA

(MINE REPORT)

By CHAS. W. HENDERSON

SUMMARY OUTLINE

	Page		Page
Summary	471	Mining and metallurgic industry	473
Calculation of value of metal production	471	Metallurgic recovery	473
Mine production by counties	473	Review by counties	474

SUMMARY

Metal mining in South Dakota is confined to a small area comprising parts of Custer, Lawrence, and Pennington Counties in the mountain group known as the Black Hills. Gold is the chief metal produced, and gold mining is the principal mineral industry of the State. Such minor minerals as columbo-tantalite, tin, beryllium, and lithium minerals have been produced. An extensive deposit of manganese-bearing shales near Chamberlain, Brule County, was mined experimentally by the International Minerals & Chemical Corporation under a War Production Board contract. Development of this project was halted early in 1943 by the War Production Board because the expenditure of manpower and equipment was not deemed advisable at that time. The Federal Bureau of Mines for a number of years has been developing the metallurgy of this deposit so that economic beneficiation may be made possible. In 1942 the recovered output of gold in the State was 522,098 fine ounces valued at $18,273,430, a 13-percent decrease from 1941. Factors contributing to the decline in gold production were: The difficulty that gold-mine operators experienced in securing adequate labor and essential supplies and the issuance of the War Production Board Gold-Mining Limitation Order in October 1942. By September 10 all but three gold mines had closed, and the order compelled another mine to close on November 26, leaving but two in operation and those only because of a reprieve. Besides gold, South Dakota in 1942 produced 186,937 fine ounces of recovered silver valued at $132,933 and 2,000 pounds of recovered copper as byproduct metals. In addition, 230,000 pounds of recovered zinc and 170,000 pounds of recovered lead were produced; this output came from a well-known zinc-lead deposit unprofitable to mine were it not for the premium prices for these metals.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

MINING AND METALLURGIC INDUSTRY

Producers of lode gold and silver in South Dakota in 1942 mined and sold or treated 1,464,384 short tons of ore yielding, in recovered metals, 522,065 fine ounces of gold, 186,934 fine ounces of silver, 2,000 pounds of copper, 170,000 pounds of lead, and 230,000 pounds of zinc. An analysis of methods of treatment shows 1,275,138 tons treated by amalgamation followed by cyanidation of sands and slimes; 179,249 tons treated by cyanidation only or by roasting followed by cyanidation; 17,614 tons (included in 179,249 tons above) treated by table and jig concentration (some of the gold concentrates were shipped to smelter and some cyanided by countercurrent-decantation cyanidation); and 9,997 tons treated by flotation concentration.

[2] From 1,143 tons of ore treated by flotation.
[3] From 17,614 tons of crude ore treated by table and jig concentration.
[4] Actually 1,602,955 pounds of calcium cyanide (48- to 49-percent strength); all reduced to equivalent of 96- to 98-percent strength to conform with earlier use of figures for high-strength NaCN and KCN.

REVIEW BY COUNTIES

CUSTER COUNTY

There were no mining operations in Custer County in 1942 other than a small amount of development work on several placer properties along French Creek. The inactivity in this district is due largely to the fact that relatively little virgin placer ground remains, and most of the residents who formerly mined have taken more lucrative jobs in war industries.

LAWRENCE COUNTY

Homestake mine.—The Homestake mine has been producing almost continuously since 1876 and has been operated since 1877 by the Homestake Mining Co. This company at first owned only the Homestake and Golden Star claims but has since acquired and consolidated into one group numerous other claims which, with the first two, constitute the Homestake mine. The annual report of the general manager of the Homestake Mining Co. for the year ended December 31, 1942, says—

Operations during 1942 were seriously affected by war conditions and by orders of the War Production Board. Difficulties began in March, when priority ratings for gold mines were lowered and culminated with the drastic order issued October 8, 1942, suspending operations of gold mines. An appeal from this order was filed with the War Production Board and modification obtained to permit hoisting and milling of broken ore for an additional period of 6 months or until June 8, 1943.

Ore production from the mine during 1942 was 1,275,138 tons which is a decrease of 14.99 percent from that for 1941. The gross income for gold and silver produced was 12.63 percent lower than in 1941. The average realization per ton was $13.39 as compared to $13.02 in 1941.

Total taxes were $4,269,162.87, which is $108,828.26 more than in 1941.

The reserve of developed ore is 19,183,683 tons, which includes 270,092 tons of broken ore remaining in the shrinkage stopes.

The mine and plant are in excellent condition and, unless circumstances arise beyond our control, this condition will be maintained in order that production can be resumed when present Government restrictions are withdrawn.

All construction was completed early in the year. The new mine and engineering office was completed and occupied in May. The Yates shaft was sunk to a depth of 145 feet below the 4,100-foot level and a skip loading station excavated below that level.

Machine shops and foundry are engaged in a variety of war production jobs.

The sawmill at Spearfish is continuing to operate at capacity. Its production of lumber is being sold largely for army bases and other construction for military purposes.

Digitized by Google

Early in the year investigation of properties that might yield metals necessary to the war effort was begun. In July an option was taken on a manganese property in Lower California. Plans for a mill are under consideration. In October, the development and operation of a deposit in Wyoming containing a strategic mineral was undertaken through an agency contract made by your subsidiary, the Wyodak Coal & Mfg. Co., with the Metals Reserve Co. Performance is guaranteed by the Homestake Mining Co. Only nominal profits at best may be expected from these operations undertaken as part of the war effort.

With the order of the War Production Board as it now stands it is expected that production from ore previously broken will continue at approximately 1,000 tons per day for the first 5 months of 1943. Expenses during the period of curtailed production and subsequent period without any production will be reduced to the minimum consistent with proper maintenance of the properties.

As a result of war conditions and the order of the War Production Board, the total number of our employees has been reduced from 2,200 to 800. This has brought distress to many and great damage to our communities. It has been with deep regret that we have been forced to release a large number of employees with long and faithful service with our company. * * * 385 former members of our staff are now with the armed forces.

Ore milled, receipts, and dividends, Homestake mine, 1938–42 [1]

Year	Ore milled (short tons)	Receipts for bullion product		Dividends
		Total	Per ton	
1938	1,377,314	$19,284,459.67	$14.0015	$9,041,760
1939	1,400,015	19,922,964.60	14.2300	9,041,760
1940	1,433,737	19,014,767.73	13.2624	9,041,760
1941	1,499,988	19,529,080.70	13.0195	9,041,760
1942	1,275,138	17,068,437.84	13.3856	7,534,800

[1] From 1876 to 1942, inclusive, this mine yielded bullion and concentrates that brought a net return of $435,610,266 and paid $149,805,802 in dividends.

Other mines.—The Bald Mountain Mining Co., second-largest producer of gold and silver in South Dakota in 1942, operated continuously throughout the year its consolidated group of mines and 370-ton cyanide mill at Trojan at an average rate of 302 tons of ore daily. Ore was produced in 1942 from the Portland, Two Johns, Dakota, Trojan, Clinton, and Empire claims. Development work done on these claims in 1942 totaled 1,932 feet of drifts and 325 feet of raises. The mill treated 131,152 tons of dry gold ore, from which 22,787 fine ounces of gold and 66,184 fine ounces of silver were recovered. About 16 percent of the ore produced was sulfide (locally known as "blue ore"), and 75 percent was oxide (locally known as "brown ore"). Following primary crushing, the refractory sulfide ores not amenable to treatment by straight cyanidation are roasted in the 110-ton gas-fired rotary hearth furnace and then returned to the mill circuit and mixed with the oxide ores for cyanidation. The net return from metals produced in 1942 after transportation and mint and smelter charges were deducted was $842,320.

At the Maitland group of claims 5½ miles northwest of Deadwood the Canyon Corporation continued operations of its 120-ton roast-cyanide mill until November 26, 1942, when the corporation closed the mine, removed the pumps, and dismantled surface buildings. Total dry gold ore treated in the mill was 30,483 tons from which 10,295 fine ounces of gold and 1,668 fine ounces of silver were recovered. Besides gold and silver, the ores contain pyrite, marcasite, fluorite, and traces of arsenic. The mine is opened by a vertical shaft 600 feet deep and by drifts and winzes.

Digitized by Google

The Belle Eldridge Gold Mines, Inc., began production of zinc-lead ore, milled on the property to make zinc and lead concentrates, from its group of claims in the Whitewood district March 12, 1942, and continued operations throughout the remainder of the year. The new 75-ton selective-flotation mill completed in March 1942 converted 9,997 tons of crude ore into 216 tons of lead concentrates and 290 tons of zinc concentrates which, combined, contained 174 fine ounces of gold, 7,946 fine ounces of silver, 2,842 pounds of copper, 193,286 pounds of lead, and 259,196 pounds of zinc. Development work in 1942 consisted of 1,020 feet of drifts, 500 feet of tunnel, and 500 feet of diamond drilling. Production came solely from the Helen Gould claim.

Placer activity in Lawrence County in 1942 was very small. The Driskill Co. handled about 2,800 cubic yards of gravel on the Little Tom placers on Potato Creek 2 miles east of Tinton with a ⅜-cubic yard power shovel and land dredge and recovered 14.5 fine ounces of gold and 1 fine ounce of silver. Other placer activity, chiefly on Bear Butte Creek in the Bear Butte district and Whitewood Creek in the Whitewood district, consisted of nine small hand-sluicing and panning operations which produced a total of only 13.5 fine ounces of gold and 2 fine ounces of silver.

PENNINGTON COUNTY

The Holy Terror Mining Co. operated its Holy Terror-Keystone mine and 100-ton cyanide mill in the Keystone district continuously until September 10, 1942, treating 17,614 tons of dry gold ore. A jig and table in the ball-mill circuit produced concentrates, part of which were shipped to the Helena (Mont.) smelter of the American Smelting & Refining Co. Most of the concentrates produced were treated in the countercurrent-decantation cyanidation circuit of the mill. Development work completed in 1942 consisted of unwatering 200 feet of shaft and driving 960 feet of drift.

Only three small hand-sluicing or panning placer operations were conducted in Pennington County in 1942—the Gold Run in the Hill City district and the Rockerville and Golden Rule in the Rapid Creek district. These placers yielded a total of only 5 fine ounces of gold.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN TEXAS

(MINE REPORT)

By CHAS. W. HENDERSON

SUMMARY OUTLINE

	Page		Page
Summary	477	Smelting and refining plants in Texas	479
Calculation of value of metal production	477	Mines review by counties	479
Mine production	478		
Ore classification	478		

SUMMARY

Texas mines produced gold, silver, copper, and lead in 1942 valued at $534,894, in terms of recovered metals; this value, compared with $812,727 in 1941, represents a decline of 34 percent, due largely to the 39-percent slump in silver output. Gold declined slightly, and lead remained virtually at the 1941 figure; but copper increased more than 1500 percent in quantity. No zinc has been recovered from ores mined in Texas since 1917.

Silver, the principal metal produced in Texas, was first found in 1880 at the Presidio mine at Shafter, Presidio County, but shipments of bullion were not begun until 1885. From that date until September 1942 this mine was by far the outstanding producer of the State—chiefly of silver but also of gold and lead. Other mines producing more than 1,000 ounces of silver in 1942 were the Bird mine in Brewster County, the Hazel mine in Culberson County, and the Sancho Panza mine in Hudspeth County. The American Metal Co. of Texas operated the Presidio mine and 400-ton cyanidation mill at Shafter continuously until September 6, 1942, when the company ceased operations. About 3,500 tons of silver smelting ore, carrying some copper, were shipped from the Sancho Panza mine near Allamoore to the El Paso smelter. About 470 tons of copper ore from the Hazel mine, 23 tons of silver ore from the Needle Peak mine, and 139 tons of lead ore (containing silver) from the Bird mine were shipped to the El Paso smelter.

Prices of gold, silver, copper, lead, and zinc, 1938–42

Year	Gold [1]	Silver [2]	Copper [3]	Lead [4]	Zinc [4]

SMELTING AND REFINING PLANTS IN TEXAS

In 1942 two zinc retort smelters (one of which has a cadmium-recovery plant), one copper smelter, one lead smelter, one antimony smelter, one tin smelter, one electrolytic plant for extraction of magnesium from sea water, and one electrolytic copper refinery were operating in Texas; a new electrolytic zinc smelter was completed and set in operation.

The American Smelting & Refining Co. continued to operate its copper and lead smelters at El Paso in 1942, treating ores purchased from operators in Arizona, New Mexico, Texas, and Utah and in Mexico. Ores from Canada, South America, Africa, and many other foreign sources continued to be received (as in 1941) at El Paso after their original destinations had fallen into enemy hands. The El Paso plant contains a unit for recovering arsenic in addition to the lead and copper furnaces.

The American Smelting & Refining Co. gas-retort zinc smelter at Amarillo was operated virtually at capacity throughout the year, treating zinc concentrates purchased from operators in Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, and South Dakota and in Mexico. The electrolytic zinc plant recently completed by the company at Corpus Christi, designed to operate on zinc concentrates from Buchans, Newfoundland, was opened on stored Buchans concentrates and Mexican concentrates.

The Machovec gas-retort zinc smelter of the American Zinc, Lead & Smelting Co. at Dumas, purchased from the Illinois Zinc Co., was operated at maximum capacity throughout the year on zinc concentrates from operators in New Mexico, Utah, Mexico, and Newfoundland. Operation of the cadmium plant was entirely satisfactory, and production of cadmium will be substantially increased during the second quarter of 1943. According to the contract with the Defense Plant Corporation, as of July 1942, the American Zinc, Lead & Smelting Co. installed additional slab zinc-producing facilities at the Dumas plant, some of which were in production before the end of 1942.

The Nichols electrolytic copper refinery at El Paso, a unit of the Phelps Dodge Corporation, continued to refine copper anodes produced at corporation smelters in Arizona. The plant was operated at capacity throughout the year.

MINES REVIEW BY COUNTIES

Brewster County.—The Bird mine 5 miles northwest of Altuda was operated throughout 1942 by the Bird Mining Co., Inc., and regular shipments began on March 10, 1942, to the smelter at El Paso. Lead ore totaling 139 tons, containing 3,230 ounces of silver, 296 pounds of copper, and 77,107 pounds of lead, was shipped during 1942. Development work in 1942 comprised 700 feet of drifts and 64 feet of winze.

Culberson County.—Copper ore totaling 469 tons, containing 2,081 ounces of silver and 28,242 pounds of copper, was shipped from the Hazel mine 14 miles northwest of Van Horn to the El Paso smelter. The mine was operated by J. P. Witherspoon, lessee, with A. P. Williams as mine superintendent; it is opened by a vertical shaft 320 feet deep. A small lot (23 tons) of dry silver ore containing 415 ounces of silver and 1,002 pounds of copper was shipped from the Needle Peak open-cut near Van Horn to the El Paso smelter.

Digitized by Google

Hudspeth County.—Lessees on the Sancho Panza mine 7 miles northeast of Allamoore shipped 3,548 tons of silver smelting ore containing 2,335 ounces of silver and 172,801 pounds of copper to the smelter at El Paso. One ton of lead ore containing 1,139 pounds of lead was shipped from Sierra Blanca to the El Paso smelter by the Lancaster Lead Co.

Presidio County.—Two small lots—34 tons and 3 tons of copper ore containing 3,206 and 332 pounds of copper, respectively—were shipped from Shafter to the smelter at El Paso.

The American Metal Co. of Texas operated its Presidio mine at Shafter continuously until September 6, 1942, when the company ceased all operations; shortly afterward all the equipment of the property was dismantled and shipped. Labor difficulties, excessive water in the lower levels, lowering of the grade of ore, and depletion of ore reserves were contributory factors to closing of the property. The quantity of ore treated was 96,481 tons compared with 140,503 tons in 1941. Development work in 1942 comprised 2,124 feet of drifts and 12,421 feet of diamond drilling. The ore minerals are argentite, anglesite, cerussite, cerargyrite, and galena. In 1942 the mill produced 545,360 ounces of silver and 213 ounces of gold in cyanide precipitates, and 396 tons of table concentrates containing 22 ounces of gold, 119,344 ounces of silver, and 283,628 pounds of lead. The cyanide precipitates carried 14,852 pounds of lead dissolved by the cyanide. The concentrates and precipitates were shipped to the Carteret (N. J.) smelter.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN UTAH

(MINE REPORT)

By G. E. Woodward and Paul Luff

SUMMARY OUTLINE

	Page		Page
Summary	481	Metallurgic industry	487
Calculation of value of metal production	482	Review by counties and districts	491
Mine production by counties	485	Tintic district	493
Mining industry	486	Bingham or West Mountain district	496
Ore classification	486	Park City region	498

SUMMARY

Ores and gravels from Utah mines yielded gold, silver, copper, lead, and zinc valued, in terms of recoverable metal, at $113,552,848 in 1942 compared with $97,796,623 in 1941. The increase in output of recoverable copper accounted for most of the gain, although increases were noted in output of all metals except silver. The total gain in value of the State metal output can be credited largely to the Bingham district, although the Park City region showed a gain in gold production and the Tintic district in lead and zinc production. The Utah Copper Co. in 1942 surpassed by far its outstanding production record established in 1941 and contributed over 70 percent of the value of the total metal output of the State. The output of zinc from Tooele County increased in 1942, whereas the output of each of the other metals decreased.

The production of copper, and more particularly that of lead and zinc, in 1942 was affected by several factors. The Metals Reserve Company announced that, effective February 1, 1942, premiums of 5 cents a pound for copper and 2¾ cents a pound for both lead and zinc would be paid for these metals produced in excess of certain fixed basic quotas. Each mine or company had its basic quota fixed according to the previous year's production or through direct negotiation with the Government agency. Most mines in Utah, which were granted basic quotas under the original principle of premium payments, have since received downward adjustment favorable to the company. To broaden the scope of the premium payments for over-quota metal further, the Metals Reserve Company announced that, effective December 1, 1942, at the opening of business it would allow an additional premium for lead and two additional premiums for zinc. Eligibility for these additional premiums was based primarily on the ability of the producer to maintain the present rate of output or to insure additional output. Each case was to be considered independently by the Quota Committee, Premium Price Plan for Copper, Lead, and Zinc (War Production Board—OPA).

Although the Government stimulated the production of copper, lead, and zinc by price manipulation, the full effect of the program was not realized because of the critical shortage of suitable mine, mill, and smelter labor. The labor supply became critically low during July, August, September, and part of October. In October the Army fur-

Digitized by Google

loughed 4,000 soldiers for service in mines. Of this number, Utah mines and smelters received approximately 700. This action tended to relieve the severity of the shortage but did not insure adequate labor for operations consistent with the present demand for metals. Thus, the majority of Utah mines at the close of 1942 faced the problem of either securing additional labor or endeavoring to maintain the present personnel at levels sufficient to meet production demands.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1938–42

Year	Gold [1]	Silver [2]	Copper [3]	Lead [4]	Zinc [4]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1938	$35.00	[5] $0.646+	$0.098	$0.046	$0.048
1939	35.00	[6] .678+	.104	.047	.052
1940	35.00	[7] .711+	.113	.050	.063
1941	35.00	[7] .711+	.118	.057	.075
1942	35.00	[7] .711+	.121	.067	.093

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.
[2] Treasury buying price for newly mined silver.
[3] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Company for over-quota production but excludes value of foreign copper delivered to Metals Reserve Company for domestic consumption.
[4] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Company for over-quota production.
[5] $0.64646464. [6] $0.67878787. [7] $0.71111111.

Mine production of gold, silver, copper, lead, and zinc in Utah, 1938–42, and total, 1864–1942, in terms of recovered metals

Year	Mines producing		Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)

[1] 1864–1901: Figures not available; 1902–42: 456,347,638 tons produced.
[2] Short tons.

Gold.—Utah mines in 1942 produced 391,544 ounces of recoverable gold—the greatest output in any year in the history of the State. By far the largest portion of Utah gold is recovered as a byproduct of the recovery of base metals; as a consequence, the gold order issued by the Government in October 1942 did not affect the State output greatly. Most mines producing siliceous ores were allowed to continue operation, so that an adequate supply of fluxing material might be available to smelters in the Salt Lake Valley. Copper

Digitized by Google

ore yielded 75 percent of the total gold and siliceous ore 10 percent; the remainder came from zinc-lead ore and slag, lead ore, lead-copper ore, zinc ore, zinc-lead-copper ore, and placers. The placer output of fine gold in 1942 was only 32 ounces. Ores of all classes treated in concentrating mills yielded 86 percent of the State total, ores shipped direct to smelters 12 percent, and ores treated by amalgamation and cyanidation, placers, and slag fumed 2 percent. Ore of the West Mountain (Bingham) district was by far the most important source of gold and in 1942 yielded 327,258 ounces (nearly 85 percent of the State total), a gain of 52,139 ounces over 1941. Gold produced from the Tintic district was slightly less than in 1941, owing to the smaller output of siliceous ores. The recoverable gold pro-

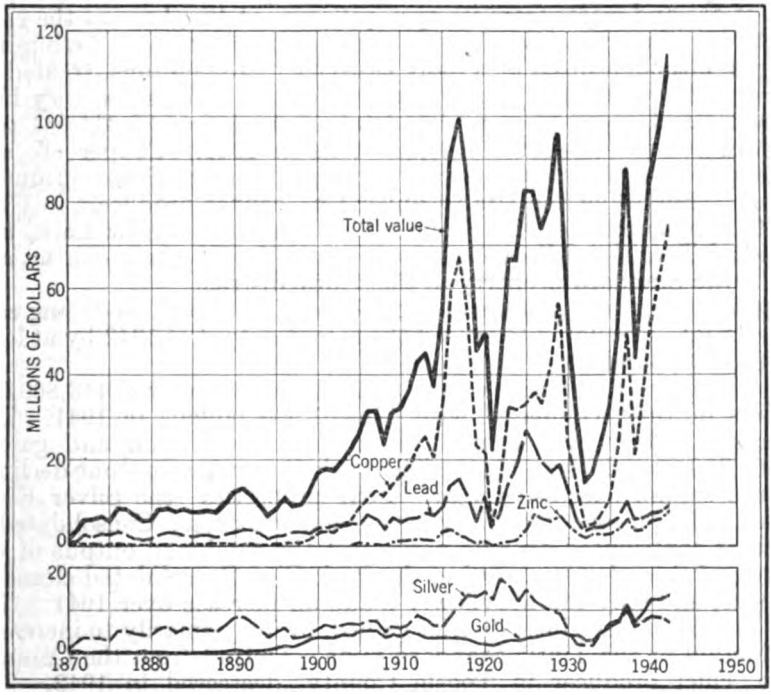

FIGURE 1.—Value of mine production of gold, silver, copper, lead, and zinc and total value in Utah, 1870-1942.

duction from the Park City region increased 3,188 ounces, owing to increases at the New Park Mining Co. Gold output from Tooele County decreased 18,523 ounces. The Utah Copper Co. produced 73 percent of the State output of gold and was followed by the United States & Lark, Mayflower, Tintic Bullion, Snyder Mines, Inc. (at Mercur), Sacramento, Mammoth, and Boston Consolidated mines; these eight properties produced 91 percent of the total gold output of Utah.

Silver.—The output of recoverable silver in Utah in 1942 was 10,574,955 ounces, of which 82 percent was derived from base-metal ore. Zinc-lead, zinc-lead-copper, and zinc ore yielded 49 percent of the State total, copper ore 26 percent, siliceous ore 18 percent, and lead and lead-copper ores 7 percent. Ore concentrated yielded 74

Digitized by Google

percent of the total and ore shipped crude to smelters virtually all the remainder. The Bingham district—chief source of silver in Utah—was followed by the Park City region, Tintic district, and Tooele County. The Utah Copper Co. was again the chief silver producer in the State; it was followed by the United States & Lark, Tintic Standard, Silver King Coalition, Park City Consolidated properties, Mayflower, Park Utah Consolidated group of properties, and Calumet; and these eight properties produced 82 percent of the silver output of Utah in 1942.

Copper.—Production of recoverable copper in Utah in 1942 was 613,382,000 pounds and completely eclipsed the former record of 533,676,000 pounds in 1941. The Utah Copper Co., by far the largest copper producer in the United States, mined about 75,000,000 tons of ore and waste from its open-pit mine at Bingham at the ratio of 1¼ tons of waste to 1 ton of ore. The company mills at Arthur and Magna, although rated at a daily capacity of 78,000 tons, treated an average of over 91,000 tons a day and continued to show very high recoveries. Copper ore mined in Utah amounted to 33,611,061 tons in 1942 compared with 30,444,402 tons in 1941. Copper ore and mine-water precipitates yielded virtually the entire State output of copper. Following the Utah Copper Co., copper producers in Utah in 1942 included the Ohio Copper Co., United States & Lark, and National Tunnel & Mines Co. properties in the Bingham district and the Tintic Standard property in the Tintic district.

During the first 3 months of 1943, Utah mines were producing copper at a rate calculated to exceed the record output of 1942 by at least 15,000,000 pounds.

Lead.—Mine production of recoverable lead in Utah was 143,860,000 pounds in 1942, compared with 139,202,000 pounds in 1941. The Bingham district was again the chief source of lead and gained 10,967,300 pounds over 1941. The Park City region output declined for the second successive year. Four properties—the Silver King, Park Utah Consolidated, Mayflower, and Park City Consolidated—together contributed over 95 percent of the total lead output of the region; of these four properties, the Park City Consolidated closed in October, and only the Mayflower made an increase over 1941. The lead output of the Tintic district gained, owing primarily to increased production at the Tintic Standard mine. Output from the Calumet mine, chief producer in Tooele County, decreased in 1942. The United States & Lark properties in the Bingham district continued to be the largest source of lead in the State, followed by the Silver King Coalition, Tintic Standard, Park Utah Consolidated, Calumet, Mayflower, and Chief Consolidated; these seven producers supplied 85 percent of the State total output of lead.

Production reports during the first 3 months of 1943 indicate that the recoverable lead output of Utah will be higher in the year 1943 than it was in 1942.

Zinc.—Output of recoverable zinc from Utah ores and slags amounted to 91,086,000 pounds in 1942 compared with 84,098,000 in 1941. Zinc recovered from old and current slag fumed accounted for the gain, as zinc recovered from zinc-lead ore declined. As in former years, the bulk of the recovered zinc came from ores of the Bingham district and Park City region, and although there was a gain in zinc output in the Bingham district it was more than

Digitized by Google

offset by losses in the Park City region. Substantial gains were noted in the output of zinc from the Tintic district in 1942, but the district is still of minor importance compared with the Bingham and Park City areas. All the zinc and zinc-lead concentrates produced in Utah in 1942 were treated at plants of the Anaconda Copper Mining Co. at Anaconda and Great Falls, Mont. Zinc fume derived from the fuming of current slag, old slag, and a small quantity of zinc ore was first deleaded and then shipped to Hillsboro, Ill., and Bartlesville, Okla., for further treatment. The zinc recovered from the fuming of current slag has not been credited entirely to Utah; the zinc ultimately recovered in the fuming operation, which originates in ores and concentrates containing at least 10 percent zinc, has been credited to the State of origin. The principal producers of zinc in Utah in 1942, named in order of output, were: United States & Lark mines, Tooele slag-fuming plant, Silver King Coalition, Park Utah Consolidated Mining Co., Mayflower, Calumet, Chief Consolidated properties, Park City Consolidated Mining Co. (closed in October 1942), and Butterfield group; these nine properties produced 97 percent of the State total zinc output.

According to calculations based on reports received during the first 3 months of 1943, the recoverable zinc output of Utah in 1943 will exceed that in 1942 by about 6,000,000 pounds.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Utah in 1942, by counties, in terms of recovered metals

County	Mines producing		Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)

MINING INDUSTRY

The production of copper ore (96 percent of the State total ore) dominated the mining industry in Utah in 1942. The Bingham district produced ore of all classes, representing 97 percent of the State total. Of the 34,087,179 tons of ore produced in the Bingham district in 1942, copper ore constituted 99 percent; virtually all the remainder was zinc-lead ore and lead ore. The grade of the copper ore and zinc-lead ore was about the same as in 1941. The bulk of the ore mined in the Park City region in 1942 was zinc-lead ore; this ore showed a lowering of zinc, lead, and silver content compared with 1941. The Tintic district again made a large gain in output of zinc-lead ore, but almost all was mined from the lower workings of the Chief Consolidated properties. The output and grade of zinc-lead ore mined in Tooele County decreased. Production of siliceous ore declined from 1941, and much of the output came from old mine and tailings dumps; the largest decline was noted in gold ore from Tooele County. The Camp Floyd district in Tooele County and the Tintic district in Juab and Utah Counties supplied 87 percent of the siliceous ore of the State.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Digitized by Google

Ore sold or treated in Utah in 1942, with content in terms of recovered metals

[1] Includes 32,062,916 pounds recovered from mine-water precipitates.
[2] Includes 87,831 tons of zinc-lead slag.
[3] A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.
[4] Includes 13,418,668 pounds recovered from mine-water precipitates.

METALLURGIC INDUSTRY

In 1942, mines in Utah produced 34,981,655 tons of ore—the greatest quantity in the history of the State—surpassing the former record of 1941 by 3,028,838 tons. This total was treated as follows: 34,336,812 tons at concentrating mills compared with 31,205,481 tons in 1941; 94,827 tons at cyanide mills compared with 252,080 tons in 1941; 1,475 tons at amalgamation mills compared with 515 tons in 1941; 460,710 tons shipped crude to smelters compared with 465,083 tons in 1941; and 87,831 tons (zinc-lead slag) fumed compared with 29,658 tons in 1941. A considerable tonnage of siliceous ore, included in the quantity shipped crude to smelters, came from old dumps and tailings piles and was used primarily as a flux in smelting. These tailings usually were paid for according to metal content, so that the shipper would be eligible for any premium payments allowed by the Government; however, smelters at times allowed extra payments for very high silica content.

All ore cyanided was handled by two cyanide plants at Mercur, under control of Snyder Mines, Inc., and all cyanide operations were discontinued after September 17. The total of 94,827 tons of gold ore cyanided yielded 7,426 ounces of gold and 157 ounces of silver; Snyder Mines, Inc., reported the consumption of 70,000 pounds of calcium cyanide, 7,500 pounds of zinc dust, and 634,000 pounds of lime. Eleven concentrating plants were active in Utah during 1942—four plants (Arthur, Magna, Ohio Copper, and Tooele) treated 33,565,587 tons of copper ore and old tailings; four mills (Bauer, Midvale, Silver King, and Tooele), with a combined rated capacity of 4,400 tons, treated 754,925 tons of ore mostly zinc-lead, zinc-lead-copper, and zinc; two gravity-concentration mills (Tooele County and Utah County) treated 300 tons of lead and silver ores; and one flotation mill in Summit County treated 16,000 tons of old zinc-lead tailings.

Three lead and two copper smelters were active in Utah in 1942. The combined rated capacity of the lead smelters was about 1,130,000 tons of charge a year, and that of the copper smelters was 1,900,000 tons. In 1942 the smelting capacity of Utah smelters was never

Digitized by Google

reached, but during the summer and early fall a labor shortage at the Garfield smelter caused the American Smelting & Refining Co. to ship a portion of its receipts of copper concentrates to Tooele, Tacoma, and El Paso smelters. The Murray lead smelter was down part of the year owing to lack of ore and concentrates.

The following tables give details of treatment for all the ore produced in Utah in 1942.

Mine production of metals in Utah in 1942, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated	Gold	Silver	Copper	Lead	Zinc

BEAVER COUNTY

Beaver Lake district.—A shipment of silver-lead ore and copper ore from the O. K. mine comprised the only output from the Beaver Lake district in 1942.

Newton district.—Gold ore amalgamated and gold ore shipped crude to a smelter from the Walkover mine comprised the output from the Newton district in 1942.

Rocky district.—D. E. Kirk, lessee on the Montreal mine, shipped several cars of crude silver-copper ore direct to the Garfield smelter. The only other production was from the Old Hickory group, from which 4 cars of silver-copper ore were shipped direct to Garfield; the Old Hickory group is operated primarily for the tungsten in the ore.

San Francisco district.—Hall Bros. Co., Inc., largest producer in the San Francisco district, began operation on the Horn Silver mine and dump in May 1942 and continued the rest of the year. Crude gold-silver-lead ore was shipped direct to Garfield and zinc-lead ore to Bauer. Other production in the district came from the Imperial group, Mayflower, and Quad Metals mines.

Star and North Star district.—Moscow Silver Mines shipped crude zinc ore direct to the Tooele smelter and mill, and lessees shipped crude lead ore direct to Murray from the Wild Bill dump.

BOX ELDER COUNTY

Crater Island district.—A small lot of copper ore was shipped to Tooele from the Copper Blossom mine in 1942.

Promontory district.—Some crude zinc-lead ore was shipped direct to Tooele from the Lake View Carbonate mine by lessees in 1942.

IRON COUNTY

Indian Peak district (formerly called Calumet).—The New Arrowhead Mining Co. shipped crude lead ore direct to smelters in 1942 and supplied the only output from the Indian Peak district.

Stateline district.—Gold ore treated in the amalgamation-flotation mill of Etna Gold Mines, Inc., comprised the only production from the Stateline district in 1942.

JUAB COUNTY

Detroit district.—The Detroit district lies in both Juab and Millard Counties, and in 1942 the only output from the Juab County section was crude gold ore shipped to the Garfield smelter from the Clara B. and First Chance claims.

Fish Springs district.—The Utah Mine group was operated intermittently in 1942 by lessees, and the only production was a car of silver-lead ore shipped crude to Murray.

Mount Nebo district.—Lead ore shipped direct to a smelter from the Central Sultana group was the only output in the Mount Nebo district in 1942.

Tintic district.—The Tintic district, which lies in both Juab and Utah Counties, is reviewed here. The table that follows gives the metal production in each section of the district in 1942, a comparison with the total in 1941, and the grand total from 1869 to 1942.

[1] Figures not available.

In 1942 the Chief Consolidated Mining Co. operated the Chief No. 1, Gemini, Eureka Hill, and Plutus mines in Juab County. Although the bulk of the production in 1942, as in 1941, came from the Chief No. 1 mine, substantial tonnages of siliceous ores were shipped to the Garfield smelter from the Gemini mine; the production from the Eureka Hill (all siliceous ore) was materially smaller than in 1941, but that from the Plutus mine was about the same. The Chief No. 1 has large bodies of zinc-lead ore, which in 1941 were under water. After the company was granted favorable quotas and assured a premium price for the recoverable zinc and lead by the Government, an extensive dewatering program was begun. According to the company printed annual report, dewatering these lower levels of the Chief No. 1 mine and equipping and opening up the connecting winzes, all in an area of 2,000 by 800 feet, comprised most of the development work in 1942. Inasmuch as mining has now begun in this area, the company anticipates that by progression it will finally reach a mined tonnage of zinc-lead ore of over 5,000 tons per month. The ore consists predominantly of sulfides and contains about 3.5 percent lead and 7.5 percent zinc. Production in 1942, says the report, comprised 38,612 tons of siliceous ore, 671 tons of silver-lead ore, and 27,093 tons of zinc-lead ore from the Chief No. 1 mine; 6,312 tons of siliceous ore and 1,118 tons of silver-lead ore from the Gemini mine; 172 tons of siliceous ore from the Eureka Hill mine; and 795 tons of siliceous ore and 59 tons of silver-lead ore from the Plutus mine—an aggregate of 74,832 tons of ore of all classes, containing 2,867 ounces of gold, 290,666 ounces of silver, 100,539 pounds of copper, 5,271,482 pounds of lead, and 4,605,698 pounds of zinc.

The Eagle & Blue Bell, Centennial-Beck, and Victoria mines, all owned or controlled by the United States Smelting, Refining & Mining Co., were operated on company account throughout 1942. The production from these properties comprised 18,573 tons of siliceous ore, 2,274 tons of lead ore, and 112 tons of zinc-lead ore, all of which was shipped crude to smelters. The Empire group, controlled by the International Smelting & Refining Co., was operated by lessees throughout the year. Production amounted to 2,229 tons of crude gold-silver ore shipped direct to a smelter. Philip P. Clark, lessee on the Godiva mine, shipped 27,056 tons of siliceous ore and tailings to Garfield and 183 tons of lead ore to Murray. A considerable quantity of siliceous tailings and crude ore was shipped direct to the Garfield smelter from the Mammoth mine in 1942, and some zinc-lead ore was shipped to the Tooele slag-fuming plant. The

Digitized by Google

remainder of the output from the Juab County section of the Tintic district was predominantly siliceous ore and tailings, all of which was shipped crude to smelters.

The Tintic Standard Mining Co. and its subsidiary companies were again the largest producers in the Utah County section of the Tintic district. The printed annual report of these companies gives the following operating details. At the Tintic Standard mines (including the Iron Blossom) production of siliceous gold-silver ore was drastically reduced from 75,744 tons in 1941 to 36,433 tons in 1942, all of which was mined on company account; lessees produced an additional 2,086 tons of siliceous ore. This reduction was necessary because no premium payments of importance would be received on these ores owing to their low content in lead and copper. Output of lead ore was increased from 31,199 to 40,379 tons, and the lead content increased from 7,794,650 to 10,234,549 pounds. Siliceous dump ore totaling 3,891 tons was shipped from the Eureka Standard mine. Lease operations were carried on throughout 1942 on the Colorado mine, and 2,176 tons of siliceous ore were shipped direct to a smelter. At the Eureka Lilly mine ore bodies developed near the Eureka Lilly shaft were mined, and further increased production from this area can be expected.

An agreement was made between the Tintic Standard Mining Co. and the North Lily Mining Co. (operating subsidiary of the International Smelting & Refining Co.) whereby a joint operation, known as the Development Unit, was carried on for the purpose of developing portions of the Twentieth Century Mining Co. ground, in which the North Lily Mining Co. is interested, and portions of the Eureka Lilly Mining Co. property, which is controlled by the Tintic Standard Mining Co. The Tintic Standard report states that the most important work carried on during the year was the joint development with the North Lily Mining Co. The work was done from the Tintic Standard 1,450-foot level and comprised 2,568 feet of drifts and 110 feet of raises. Up to February 1943 only diamond drilling had prospected the limestone area. Good ore was encountered in one drill hole and in a vein found in a crosscut from the main drift; work is progressing at this time to further the development of these deposits. During the operation in 1942 production amounted to 1,707 tons of siliceous ore and came from that portion of the Development Unit controlled by the Eureka Lilly Mining Co.

The tonnage of ore of all classes mined by the Tintic Standard Mining Co. and its subsidiary companies, including ore from the Development Unit, aggregated 93,874 tons with the following metal content: 4,436 ounces of gold, 1,130,459 ounces of silver, 1,052,259 pounds of copper, 12,677,062 pounds of lead, and 1,295 pounds of zinc. The Harold dump of the Tintic Standard Mining Co. was worked by the American Smelting & Refining Co., and 68,980 tons of siliceous ore was shipped direct to the Garfield smelter in 1942; the ore contained over 3,500,000 pounds of lead. Active mines in the Utah County section of the Tintic district, owned or controlled by the International Smelting & Refining Co. and its subsidiaries, were the Tintic Bullion, May Day (Mountain View), Hanibal, and North Lily; these properties were operated throughout the year and produced 3,510 tons of siliceous ore and 2,606 tons of zinc-lead ore.

Trout Creek district.—The Trout Creek Mining Co. shipped a car of zinc ore to the Combined Metals Reduction Co. plant at Bauer.

Digitized by Google

MILLARD COUNTY

Detroit district.—Some copper ore was shipped crude to a smelter from the R. L. Laws and Gold Chief properties in 1942.

Kanosh district.—The Kanosh Leasing Co., operating the Blue Bell mine, shipped some crude zinc ore direct to the Tooele slag plant in 1942.

MORGAN COUNTY

Argenta district.—A test lot of lead ore was shipped crude to the Midvale smelter from the Carbonate Gem mine in 1942.

PIUTE COUNTY

Mount Baldy district.—John Pearson, lessee, operated the Deer Trail mine all of 1942 and shipped crude gold-silver ore direct to the Garfield smelter.

Ohio district.—Output from the Ohio district in 1942 was many times that in 1941 and comprised gold-silver ore and lead ore from the Bully Boy mine shipped crude to smelters and zinc-lead ore from Cascade Lot 57 shipped to the Midvale concentrator.

SALT LAKE COUNTY

Big and Little Cottonwood districts.—Base-metal ore shipped direct to smelters from the Cardiff mine supplied most of the output from the Big Cottonwood district in 1942. It included 335 tons of copper ore, 128 tons of lead ore, and 202 tons of zinc-lead ore. The Mountain Mines Co. produced 304 tons of siliceous ore which was shipped crude to the Garfield smelter. Other production in the district came from the property of the Kentucky-Utah Mining Co. and from the Richmond Teresa and Kennebec mines.

Crude lead ore from the Columbus Rexall Consolidated Mines Co. and Wasatch Mines Co. shipped direct to a smelter comprised the output from the Little Cottonwood district in 1942.

"Smelter" district.—Output from the "Smelter" district in 1942 came chiefly from the Germania dump, clean-ups at local assay offices, and clean-up of railroad yards and tracks.

West Mountain (Bingham) district.—The Bingham district, by far the most important mining region in Utah, produced over four-fifths of the gold, virtually all of the copper, and over half of the lead, silver, and zinc output of the State in 1942. The following table shows production from mines in the district in 1941 and 1942 and the total from 1865 to 1942.

Mine production of gold, silver, copper, lead, and zinc in Bingham or West Mountain district, Salt Lake County, Utah, 1941–42, and total, 1865–1942, in terms of recovered metals

Year	Mines producing	Ore	Gold (lode and placer)	Silver (lode and placer)	Copper	Lead	Zinc	Total value
		Short tons	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*	*Pounds*	
1941	15	30,866,163	275,119	4,851,872	529,409,000	69,024,000	40,991,000	$82,558,340
1942	15	34,087,179	327,258	5,399,744	609,374,900	79,991,300	45,267,100	98,597,468
Total, 1865-1942	-------	(1)	4,798,185	127,390,269	[2] 3,730,607	[2] 1,460,358	[2] 414,878	1,466,333,507

[2] Short tons.

Digitized by Google

The Utah Copper Co. easily maintained its position as the largest copper producer in the world and in 1942 surpassed by a wide margin its previous record output. The company produced over two-thirds of the State gold, about one-quarter of the State silver, and nearly all of the State copper. Ore was milled at the two flotation-concentration plants (Magna and Arthur units) at an average rate of over 91,000 tons a day compared with about 83,000 tons in 1941. The ore milled in 1942 had a slightly higher gold and silver content but a somewhat lower copper content. Mill recoveries of gold and silver were about the same as in 1941, but the average copper recovery increased about 1.5 percent. The output of molybdenum sulfide, a byproduct of the copper production, was considerably greater than in 1941. Mill recovery of byproduct molybdenum was also higher in 1942. The Magna mill was operated without a shut-down throughout the year, but the Arthur mill lost the equivalent of 6 days of operation. Copper ore and waste were mined at the open pit at Bingham, 17.5 miles from the Magna and Arthur concentrators, at the rate of 204,000 tons a day, which was about 16,000 tons greater than the rate in 1941. The waste was piled in gulches adjacent to the open pit and there leached. In addition to the huge quantity of copper contained in the copper concentrates produced in 1942, over 31,000,000 pounds of copper were contained in the copper precipitates made in the precipitating plant at Lead Mine. Owing to the vast quantities of gold, copper, and molybdenum produced in 1942, the Utah Copper Co. was the leading copper producer and the second-largest molybdenum producer in the United States and ranked high among the gold producers. According to reports received during the first 3 months of 1943, the company is again surpassing any previous output.

The Boston Consolidated property, owned by the Utah Copper Co., was operated all of 1942 by the American Smelting & Refining Co. Crude copper and lead ore was shipped direct to smelters.

Zinc and lead output of the Bingham district, which made notable gains compared with 1941, came largely from the United States & Lark property of the United States Smelting, Refining & Mining Co. In 1942 the company mined and shipped to its Midvale flotation-concentrator about 18 percent more zinc-lead ore than in 1941, of about the same gold, silver, and zinc content but of a slightly higher lead content. Crude gold-silver and lead ores shipped direct to a smelter amounted to about 26,000 tons. The mine was easily the largest producer of lead and the second-largest producer of zinc in the Western States. The gold and silver output was exceeded only by that of the Utah Copper Co. Extensive development work completed in 1942 comprised 20,911 feet of shafts, drifts, and raises and 1,464 feet of diamond drilling. Reports received during the first 3 months of 1943 indicated that in 1943 the company will produce slightly more zinc than in 1942 and about the same quantity of lead. Other properties owned or controlled by the United States Smelting, Refining & Mining Co., active in 1942, included the Niagara, the Montana-Bingham Consolidated, Bingham Metals, and Utah Metal. The total ore of all classes produced from these properties amounted to 20,378 tons in 1942.

The Apex Delaware group was operated the entire year by the National Tunnel & Mines Co. The property, worked through the

Digitized by Google

Elton tunnel completed in 1941, produced ore of several classes. Output in 1942 of zinc-lead ore was only 5,000 tons, but the rate of production paralleling the development of ore bodies had reached over 1,000 tons a month in December. Development and rehabilitation work on the copper ore bodies of the mine had reached a stage in May 1942 permitting the company to produce copper milling ore at the rate of over 6,000 tons a month; this was gradually increased until in December copper ore was produced at a rate exceeding 10,000 tons a month. In addition to the copper and zinc-lead milling ore produced, 285 tons of gold and lead ores were shipped direct to smelters.

The Ohio Copper Co. treated 410,075 tons of old gravity and flotation tailings, which contained about 8 pounds of copper per ton. From these tailings 4,368 tons of copper concentrates were made, which averaged 25 percent copper. The capacity of the combination acid leaching and flotation mill was increased from 1,000 to 1,500 tons a day. The treatment process involves sluicing the old tailings to the mill. There the pulp is conditioned for half an hour with sulfuric acid; the soluble copper is then precipitated on shredded cans in the pulp. The pulp containing the precipitated copper and sulfide copper then goes through the flotation section of the mill. The resulting concentrate is thickened and filtered.

A total of 26,754 tons of ore of all classes was shipped from the Butterfield group to the Combined Metals Reduction Co. plant at Bauer and to the International Smelting & Refining Co. at Tooele; the total output was about 5,000 tons less than in 1941.

Other producers active in the Bingham district in 1942 included the Bingham Congor, Chicago Silver, Kremlin, Kaighn, and property of the Victory Mines Co.

SAN JUAN COUNTY

The only lode production from San Juan County in 1942 came from crude copper ore shipped direct to smelter from the Lisbon mine in the La Sal district.

SEVIER COUNTY

Henry district.—A small lot of crude gold-silver ore was shipped to Garfield in 1942 from the B. W. & H. property; it comprised the output of the district.

SUMMIT AND WASATCH COUNTIES

PARK CITY REGION

The Park City region includes the Uintah district in Summit County and the Blue Ledge and Snake Creek districts in Wasatch County. Production of all metals except gold decreased in 1942, as indicated in the following table which gives the output from the region in 1941 and 1942 and the total since 1870.

Digitized by Google

Mine production of gold, silver, copper, lead, and zinc in Park City region, Summit and Wasatch Counties, Utah, 1941–42, and total, 1870–1942, in terms of recovered metals

Year	Mines producing	Ore	Gold	Silver	Copper	Lead	Zinc	Total value
		Short tons	*Fine ounces*	*Fine ounces*	*Pounds*	*Pounds*	*Pounds*	
1941	12	337,595	19,747	3,271,199	1,507,000	38,188,000	32,353,000	$7,798,348
1942	15	279,748	22,935	2,632,109	1,454,700	30,556,800	26,051,700	7,320,580
Total, 1870–1942		(1)	496,320	229,300,243	64,782,213	2,318,503,634	611,104,611	344,200,148

[1] Figures not available.

Output from the Silver King Coalition mine and its 800-ton flotation plant was substantially lower than in 1941, owing chiefly to inadequate labor supply. In one period of 1942 employment was only 55 percent of maximum. Under the premium-pay plan the company monthly quota of metal production was set at 567 tons of metallic lead and 472 tons of metallic zinc. As of August 1942 this quota was cut to 150 tons of lead and 125 tons of zinc. The company printed annual report states that mining operations produced 90,824 tons of ore (116,443 in 1941), which comprised 220 tons of crude lead ore and 90,604 tons of zinc-lead milling ore. The latter produced 9,324 tons of lead concentrates and 8,751 tons of zinc concentrates. The total metallic content of the concentrates and crude smelting ore was 1,315 ounces of gold, 854,233 ounces of silver, 452,758 pounds of copper, 12,541,423 pounds of lead, and 10,895,594 pounds of zinc. Development work during 1942 totaled 22,595 feet of drifts, raises, winzes, and shafts; 500 feet of diamond drilling were completed. Recent developments have so improved the physical condition of the property that, assuming an adequate labor supply, 1943 should prove a more productive year.

The Park Utah Consolidated Mines Co. operated the Park Utah Consolidated Mines group in Summit County and the Keetley unit in Wasatch County continuously in 1942. All the ore produced was sent to the International Smelting & Refining Co. plants at Tooele for further treatment. According to the company printed annual report, production from the Park Utah Consolidated group of mines was 60,972 tons of ore containing 3,846 ounces of gold, 371,122 ounces of silver, 11,091,618 pounds of lead, 11,425,019 pounds of zinc, and 351,425 pounds of copper. This production was materially lower than in 1941, owing primarily to the shortage of efficient labor and the low price for metals set by the Government for the first 8 months of the year. Some relief was obtained in September 1942, when the premium allowance was adjusted for lead and zinc. Immediately after this was granted, operations were changed from a 5-day two-shift to a 6-day two-shift basis, and development footage was increased. Because of the favorable response to this new development, further negotiations for premium revision were started. These new negotiations were concluded favorably to the company, and unwatering of the lower levels of the Ontario and Utah units was begun and the rate of development increased further in horizons above the water level in these two units. If a shortage of manpower does not

Digitized by Google

delay progress, it is expected that enough ore will be uncovered to increase the present rate of production. The Park City Utah Mines group (Keetley unit) in Wasatch County shipped 6,302 tons of ore of all classes to the International mill and smelter for treatment. In addition, the Park Utah Consolidated Mines Co. handled all the operations at the Daly group and shipped about 1,500 tons of zinc-lead ore to the International mill.

The Park City Consolidated Mines Co. operated in 1942 until August, when the company began closing the property; the final shipment of ore was made October 10. The company reports that during the operating period 40,944 tons of ore were shipped to Midvale and contained 2,299 ounces of gold, 674,024 ounces of silver, 128,287 pounds of copper, 1,460,935 pounds of lead, and 2,542,725 pounds of zinc. Increased operating cost was the stated reason for closing the property.

Gold-silver-copper-lead-zinc ore shipped to the Midvale concentrator by the New Park Mining Co. amounted to 49,947 tons compared with 58,600 tons in 1941. The ore shipped to Midvale in 1942 was considerably higher in grade; it contained 16,591 ounces of gold, 641,203 ounces of silver, 798,885 pounds of copper, 6,451,642 pounds of lead, and 7,333,470 pounds of zinc, an output surpassing that in 1941 by a wide margin. The company was by far the leading gold producer in the Park City region. Development work completed totaled 4,656 feet of shafts, drifts, crosscuts, and raises and 2,145 feet of diamond drilling. During 1942 ore was developed in the limestones as well as in the igneous (diorite rock) formations.

D. C. Despain operated the American Flag property under lease for 8 months in 1942; during this time 1,490 tons of gold-silver ore were shipped crude to a smelter. A car of silver ore and a car of zinc-lead ore were shipped from the property of the New Quincy Mining Co.

Old tailings shipped to smelters and old tailings remilled comprised the remaining production from the Park City region in 1942. A total of 27,363 tons of tailings was treated; of this total 16,000 tons were remilled and the zinc-lead middlings produced were shipped to the Midvale concentrator, and 11,363 tons consisted of siliceous silver tailings shipped direct to the Garfield smelter. The most important operations included those of Reuben Garbett, William Wortley, the American Smelting & Refining Co., Marion Lewis, and C. D. Clegg.

TOOELE COUNTY

Tooele County ranked fourth among the metal-producing areas in Utah in 1942. Mines in the county produced gold, silver, copper, lead, and zinc valued at $3,179,414 compared with $2,892,899 in 1941. This gain was due primarily to output from the Tooele slag-fuming plant, which more than offset losses from other districts.

Camp Floyd district.—Gold output from the Camp Floyd district, only important straight gold-producing district in Utah, was cut drastically in 1942. The total value of the output was $436,855 in 1942 compared with $1,049,610 in 1941. Snyder Mines, Inc., continued to be the largest gold producer in the district and treated over 94,000 tons of ore by cyanidation from both company and custom operations. In addition to the cyanide milling operations, over 21,000

Digitized by Google

tons of highly siliceous gold ore were shipped direct to Garfield for flux. The smelter continued to receive fluxing material from the Camp Floyd district throughout 1942. The principal producers were Snyder Mines, Inc., and the Sacramento Gold Mining Co.

Clifton district.—A small lot of crude lead ore was shipped direct to smelters from the Clifton Standard group in 1942.

Dugway district.—Crude lead ore was shipped direct to the International smelter and zinc-lead ore to the Bauer mills from Four Metals Mines, only active property in the district in 1942.

Erickson district.—The Dollar mine produced zinc-lead and lead ore in 1942, which was shipped crude to the International smelter.

Lakeside district.—Output in the Lakeside district in 1942 comprised crude lead ore from the Monarch mine and crude lead ore and zinc-lead ore from the Georgia Lyn mine shipped direct to a smelter, and lead ore milled.

North Tintic district.—Operators of the Scranton mine shipped crude lead and zinc ore direct to smelters in 1942.

Ophir district.—The total value of metal production from the Ophir district increased in 1942 compared with 1941, owing to the increased output of lead and zinc. The Hidden Treasure mine, largest producer in the district, was operated throughout 1942 by the United States Smelting, Refining & Mining Co.; ore of all classes produced amounted to 6,457 tons, an increase of about 800 tons over 1941. The Star Lease operated the Ophir Queen claim throughout 1942 and shipped lead and zinc-lead ore to the Midvale concentrator and smelter. Several other mines in the district were active in 1942, the most important being the Togo, Ophir Hill, and Mono group.

Rush Valley district.—The West Calumet (Calumet), owned and operated by the Combined Metals Reduction Co., was in 1942 again by far the largest producer in the Rush Valley district; 36,089 tons (38,455 in 1941) of zinc-lead ore were shipped to the Bauer mill, and 918 tons of crude lead ore were shipped direct to the International smelter. Gold ore was shipped direct to Garfield from the Blue Eagle mine. Other production included ore of several classes from the Silver Eagle mine, lead ore from the Bluestone mine, gold-silver and zinc-lead ores from the Honerine-Galena King, and lead ore from the Emilie mine.

"Smelter" district.—The International Smelting & Refining Co. operated its slag-fuming plant throughout 1942, and the output of lead and zinc more than trebled compared with 1941. Although the slag-fuming plant treated in all over 119,000 tons of molten slag, cold slag, and crude ore, Utah received production credit for the metal yield from only 87,831 tons; the difference represents material credited to the States in which the original slag-making material originated. The lead blast furnace of the International Smelting & Refining Co. is adjacent to and works in conjunction with the slag furnace. The plants have been thus arranged for convenience of operation as well as to allow the company to extract, with high recoveries, any gold, silver, copper, and lead that are contained in the crude ores, concentrates, old slags, etc., received before the material is treated for the recovery of zinc. The zinc fume produced averaged 71 percent zinc and the lead fume 49 percent lead.

Digitized by Google

Willow Springs district.—The production in the Willow Springs district came from rich gold ore, lead ore, and zinc-lead ore shipped direct to smelters. The Oro Del Rey mine was by far the outstanding producer.

UTAH COUNTY

American Fork district.—The Dutchman mine was again the largest producer in the American Fork district and in 1942 shipped 299 tons of high-grade zinc-lead ore to Midvale and a few tons of zinc ore to Tooele. Other producers included the Blue Rock and Pacific, Globe, and Live Yankee mines.

Tintic district.—Mines in the Utah section of the Tintic district are reviewed under Juab County.

WASHINGTON COUNTY

Bull Valley district.—A little gold ore from the Bull Run mine was amalgamated in 1942.

Tutsagubet district.—Copper ore and lead ore were shipped direct to smelters from the Apex mine in 1942.

WAYNE COUNTY

A test lot of silver ore was shipped direct to a smelter from the Copper Queen mine in the Hanksville district in 1942.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN WASHINGTON

(MINE REPORT)

By G. E. Woodward and Paul Luff

SUMMARY OUTLINE

	Page		Page
Summary	503	Metallurgic industry	508
Calculation of value of metal production	503	Review by counties and districts	512
Mine production by counties	506	Chelan Lake district	513
Mining industry	507	Republic district	513
Ore classification	507	Metaline district	514

SUMMARY

Mines in Washington yielded gold, silver, copper, lead, and zinc valued, in terms of recoverable metal, at $8,172,609 in 1942 compared with $7,874,886 in 1941. The output of lead and zinc increased, but that of gold, silver, and copper decreased; the gain in total value of the five metals was due in part to the greater output of lead and zinc and in part to the increase in price paid per unit of recoverable copper, lead, and zinc. The gain in gold production in Chelan County more than offset losses in Ferry, Stevens, and Okanogan Counties. Silver production declined in all the larger producing counties. Almost all the State output of copper was derived, as in former years, from the Holden mine of the Howe Sound Co. in Chelan County. The gain in production of lead and zinc (recovered almost entirely from three mines in Pend Oreille County and two mines in Stevens County) resulted in large measure from the substantially increased output of zinc in Stevens County and of lead in Pend Oreille County. The Pend Oreille Mines & Metals Co. continued as the major producer of both lead and zinc in the State.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1938–42

Year	Gold [1]	Silver [2]	Copper [3]	Lead [4]	Zinc [4]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1938	$35.00	[5] $0.646+	$0.098	$0.046	$0.048
1939	35.00	[6] .678+	.104	.047	.052
1940	35.00	[7] .711+	.113	.050	.063
1941	35.00	[7] .711+	.118	.057	.075
1942	35.00	[7] .711+	.121	.067	.093

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.

[2] Treasury buying price for newly mined silver.

[3] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production but excludes value of foreign copper delivered to Metals Reserve Co. for domestic consumption.

[4] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production.

[5] $0.64646464. [6] $0.67878787. [7] $0.71111111.

1941	540	18,900	90	64	18,964
1942	356	12,460	59	42	12,502

Gold.—The output of recoverable gold from lode and placer operations in Washington declined 10 percent in 1942 from 1941. The quantity recovered from placer operations has been of minor importance compared with that from lode mines, and in 1942 placers yielded only 356 fine ounces. Several factors contributed to this decline, the more important of which were shortages of labor and supplies to maintain normal operations in gold mines and the issuance of a Government order in October 1942 which resulted in the closing or greatly curtailing of operations by several small mines. The direct result of interference with normal gold-mining operations was that much less siliceous gold ore was treated. Gold recovered by amalgamation, by cyanidation, from concentrates smelted, and from crude ore shipped direct to smelters all declined; however, gold recovered from copper concentrates smelted increased. Gold recovered in bullion from ores treated at cyanidation plants (with or without concentration equipment) declined in both Ferry and Stevens Counties; in Chelan County 940 ounces of gold came from the cyanidation of current tailings, whereas none was recovered in 1941. Gold recovered

Digitized by Google

from gold concentrates made in the concentrating sections of cyanide mills in Ferry County showed a drop in 1942. Gold recovered at amalgamation mills declined in each of the counties in which such mills were operated. Gold recovered from crude ore shipped direct to smelters declined in Ferry and Okanogan Counties but increased in Chelan County. Copper concentrates produced by the Howe Sound Co. yielded 63 percent of the State total gold, and gold concentrates produced from the Knob Hill property yielded 24 percent. Other important producers of gold were the Aurum and Valley mines in Ferry County. The total output of gold ore was 93,957 tons in 1942, compared with 178,121 tons in 1941, and was treated as follows: 71,232 tons cyanided, 125 tons amalgamated, 21,150 tons shipped crude to smelters, and 1,450 tons concentrated.

Silver.—The output of recoverable silver in Washington declined 8 percent in 1942 from 1941, and declines were noted in all the larger producing counties. The largest outputs were in Chelan, Ferry, Stevens, and Pend Oreille Counties; and mines in Chelan and Ferry produced 92 percent of the State total. Copper ore yielded 48 percent of the total silver, gold ore 45 percent, and zinc-lead ore 7 percent; the remainder came from lead ore, lead-copper ore, and placers. The Holden property of the Howe Sound Co. in Chelan County was again the largest producer of silver in the State, followed by the Knob Hill property, operated by Knob Hill Mines, Inc., in Ferry County; these two properties produced 85 percent of the State total. Other producers of silver were the Aurum and Valley properties in Ferry County; the Pend Oreille Mines & Metals Co. property in Pend Oreille County; and the Zenith Mines, Inc., and Sierra Zinc Co. properties, both in Stevens County. Placer mines yielded 59 fine ounces of silver.

Copper.—The output of recoverable copper in Washington in 1942 was 16,060,000 pounds, or less than in any year since 1938 although the tonnage of copper ore treated was greater than in any previous year. The Howe Sound Co. shipped copper concentrates rich in gold from its Holden property in Chelan County and accounted for 99 percent of the State total output of copper; the value of the recoverable gold in these concentrates was equivalent to 88 percent of the value of the copper. Among other copper producers were the Sunset mine of the Kromona Mines Corporation in Snohomish County and the Lucky Boy mine in Stevens County.

Lead and zinc.—The production of recoverable zinc in Washington in 1942 was the greatest in the history of the State, exceeding that of 1941 by 156,000 pounds; the production of recoverable lead was 1,896,000 pounds greater than in 1941 and only 87,687 pounds less than in the record year 1917, when 9,789,687 pounds were produced. Three properties in Pend Oreille County produced 94 percent of the State total lead and 95 percent of the zinc; virtually all the rest of the lead and zinc recovered came from two properties in Stevens County. The lead output from Pend Oreille County was greater than in 1941, but the zinc output declined; however, this decrease was more than offset by the increase from operations in Stevens County. Zinc-lead ore treated in the two flotation mills (Pend Oreille and Grandview) in Pend Oreille County exceeded that treated in 1941 by 36,585 tons; it averaged 1.50 percent in lead and 4.70 percent in zinc, compared with 1.39 percent in lead and 5.35 percent in zinc in 1941. Zinc-lead ore

556250—43——33

Digitized by Google

treated in Stevens County totaled 14,064 tons in 1942, compared with 2,051 tons in 1941; the average grade of the ore was higher than that from mines in Pend Oreille County.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Washington in 1942, by counties, in terms of recovered metals

County	Mines producing		Gold (lode and placer)		Silver (lode and placer)

[1] A floating washing plant supplied with gravel by a dragline excavator is called a "dragline dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."

MINING INDUSTRY

Six properties in Washington produced 1,192,927 tons of ore in 1942, or 98 percent of the State output. This ore included copper ore from the Holden mine in Chelan County; zinc-lead ore from the Pend Oreille, Metaline, and Grandview properties in Pend Oreille County and the Blue Ridge property in Stevens County; and gold ore from the Knob Hill mine in Ferry County. Development work on these six properties in 1942 included completion of 19,212 feet of drifts, crosscuts, raises, shafts, and tunnels, 71,192 feet of diamond drilling, and 434 feet of churn drilling.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Washington in 1942, with content in terms of recovered metals

Source	Mines producing	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Dry and siliceous gold ore	18	93,957	26,524	165,960	10,600	600	----------
Copper ore	5	717,124	[1] 48,399	[1] 176,348	16,036,400	----------	----------

METALLURGIC INDUSTRY

Lode mines in Washington produced 1,222,937 tons of ore in 1942, treated as follows: 1,130,075 tons in straight concentration mills, 71,232 tons in cyanide mills and a cyanide-concentration mill, 125 tons in amalgamation mills, and 21,505 tons shipped crude to smelters.

Amalgamation plants.—Five straight amalgamation plants and one amalgamation and concentration plant treated 125 tons of gold ore in 1942. The Morning Star mine in Ferry County was the chief producer.

Cyanidation mills.—The cyanide plant at the Holden mill of the Howe Sound Co. operated about 8 months in 1942, during which time 180,000 tons of current tailings from copper ore were treated. The 400-ton Knob Hill cyanide-concentration mill treated gold ore from the Knob Hill mine; the plant operated throughout 1942. The First Thought 50-ton cyanide mill was operated on ores from the First Thought property until May, when the property was closed. These three plants treated 247,732 tons of ore and current tailings (180,000 tons) and reported the consumption of 307,465 pounds of calcium cyanide, 4,000 pounds of sodium cyanide (91-percent grade), 20,775 pounds of zinc dust, 1,460 pounds of lead acetate, 2,600 pounds of lead nitrate, and 856,220 pounds of lime.

Concentration mills.—A total of 1,130,075 tons of ore was treated at 11 flotation mills, as follows: 716,928 tons of copper ore at 3 mills, 411,690 tons of zinc-lead ore at 5 mills, and 1,457 tons of gold, lead, and lead-copper ores at 3 plants.

Details of the treatment of all ore produced in Washington in 1942 are given in the following tables.

Mine production of metals in Washington in 1942, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore [1] amalgamated	125	264	87			
Ore and tailings cyanided	[2] 247,732	3,943	18,091			
Concentrates smelted	71,492	65,422	323,029	15,991,791	9,595,622	28,796,000
Ore smelted	21,505	5,411	27,772	68,209	106,378	
Placer		356	59

ASOTIN COUNTY

Most of the gold output from Asotin County in 1942 came from the operations of three small dragline dredges on Snake River. All placer operations employing mechanical equipment closed in October 1942.

BENTON COUNTY

All the gold output from Benton County in 1942 came from two dry-land dredges operating on Columbia River.

Digitized by Google

CHELAN COUNTY

Chelan Lake district.—The Holden mine of the Howe Sound Co. continued to be the leading producer in 1942 of gold, silver, and copper in Washington. The company treated 715,726 tons of copper-zinc ore, which averaged 0.083 ounce of gold and 0.308 ounce of silver to the ton, 1.21 percent copper, and 1.02 percent zinc. The quantity of ore treated was 28,383 tons greater than in 1941 but of lower copper content; as a consequence, the copper output of the State declined. The company long has been treating large tonnages of ore of about equal zinc and copper content, but it was not until 1942 that steps were taken to recover the zinc. In 1942 equipment was added to the mill whereby zinc concentrates as well as copper concentrates were to be recovered, but actual recovery of zinc concentrates did not begin until late in December of that year. The rated milling capacity of the 2,000-ton concentrator was not increased in 1942, although an average of 2,101 tons of ore a day was treated compared with 2,056 tons in 1941. The cyanide plant, added to the concentrator late in 1941, treated current tailings from the copper ore until September 6, 1942, when it was closed. During the operating period 180,000 tons of current tailings were treated and resulted in the recovery of 940 ounces of gold and 2,557 ounces of silver. Development work in 1942 included sinking 347 feet of vertical shaft, driving 8,031 feet of drifts, and 2,862 feet of raises, besides completing 19,507 feet of diamond drilling. The total footage of development work done in 1942 was equivalent to about half that completed in 1941.

Peshastin Creek district.—Gold ore shipped crude to the Tacoma smelter from the Polepick mine was the only production in the Peshastin Creek district in 1942.

FERRY COUNTY

Danville district.—The Morning Star Mining Co. operated its gold property in 1942 from January to May and in December and produced about half the quantity of metals produced in 1941. The intervening period was spent in developing an adjoining copper property.

Republic district.—Siliceous ore, from which the entire metal output of the Republic district was recovered, amounted to 87,999 tons in 1942 and comprised 67,452 tons cyanided and 20,547 tons shipped direct to smelters. Knob Hill Mines, Inc., was again the chief producer in the district but treated ore from the Knob Hill mine only; it handled 67,452 tons of gold ore in its 400-ton flotation-cyanidation mill, producing 3,500 tons of gold concentrates in addition to cyanide bullion. The company announced that development work in 1942 included 2,459 feet of diamond drilling and 434 feet of churn drilling; also, that all open-cut mining was discontinued.

The Aurum Mining Co. operated the Aurum group throughout 1942 and continued to supply most of the crude ore shipped direct to smelter from the Republic district. The Valley mine produced about 5,800 tons of highly siliceous gold ore, which was shipped direct to the Tacoma smelter. Other producers of gold ore shipped direct to smelters included the Republic group, operated by the Eureka Mining & Milling Co., and the South Penn property.

Digitized by Google

GRANT COUNTY

A dragline dredge operated by Miller Bros. at Chinaman Bar on Columbia River accounted for all the gold recovered in Grant County in 1942.

KITTITAS COUNTY

Some placer gold was recovered from sluicing and hydraulic operations in 1942 from gravels in the Swauk and Yakima River districts.

OKANOGAN COUNTY

Cascade district.—Metal from crude gold ore shipped direct to the Tacoma smelter from the Bodie group near Wauconda comprised the output from the Cascade district in 1942.

Methow district.—The Methow M & M Co. treated gold ore in a small concentrating mill in 1942 and was the largest producer in the Methow district. Other producers were the Highland Light & Hidden Treasure, Alder group, and Crystal Mountain group of properties.

PEND OREILLE COUNTY

Metaline district.—Most of the recovered lead and zinc from Washington in 1942 was derived from the zinc-lead ores of the Metaline district. The value of the recovered metals increased from $2,573,300 in 1941 to $3,150,270 in 1942 as the result of an increased output of lead and a higher unit price for lead and zinc. The Pend Oreille Mines & Metals Co., chief producer in the district, operated its Josephine group of properties throughout the year and treated an average of 642 tons (based on a 365-day year) of zinc-lead ore per day in its 700-ton flotation mill. The average grade of the ore treated in 1942 was 1.66 percent lead and 4.28 percent zinc, compared with 1.11 percent lead and 4.84 percent zinc in 1941. The lead concentrates produced averaged about 78 percent, and the zinc concentrates averaged 62 percent. Mine development, according to the company report, amounted to about 18,000 feet of diamond drilling and the driving in aggregate of about 2,700 feet of tunnel, raises, and shafts. The company also reported the opening of the 1,000-foot and 1,500-foot levels. Most of the remainder of the lead output of the district and all the zinc were contained in the high-grade lead and zinc concentrates produced at the Grandview mill of the American Zinc, Lead & Smelting Co. The capacity of this mill, which treats zinc-lead ore from the properties of the American Zinc, Lead & Smelting Co. and the Metaline Mining & Leasing Co., was increased from 450–500 tons a day to 600 tons by adding classifying capacity in 1942. The Grandview mill treated about 22,000 tons of ore more than was treated in 1941, but the average lead and zinc content of the mill ore was lower. The American Zinc, Lead & Smelting Co. reported that mine development comprised completion of 12,028 feet of diamond drilling and 1,512 feet of drifts. The Metaline Mining & Leasing Co. reported that development comprised completion of 19,131 feet of diamond drilling, 3,058 feet of drifts, and 130 feet of shaft. Other production in the district included lead ore shipped crude to a smelter from the Cliff and Velvet Lode properties.

Digitized by Google

SNOHOMISH COUNTY

Index district.—The Kromona Mines Corporation, only active producer in the Index district in 1942, shipped crude copper ore direct to a smelter and also produced some copper concentrates. The company output was substantially lower than in 1941.

Sultan district.—Some copper ore was shipped crude to a smelter from the property of the Pacific Nickel Co. A little placer gold was recovered from sluicing along Sultan River.

STEVENS COUNTY

Bossburg district.—The Bonanza mine, an old property near Evans, was reopened by Russell Parker in June; equipment was installed, and operations were begun the latter part of the month. During the remainder of the year the property produced 100 tons of lead ore, containing 585 ounces of silver and 54,994 pounds of lead. A 60-ton concentration mill is to be installed early in 1943.

Deer Trail district.—Zenith Mines, Inc., operated the Cleveland mine during 1942 and treated 1,859 tons of zinc-lead ore in a small flotation mill. The ore treated averaged about 6 percent lead and 7 percent zinc.

Kettle Falls district.—A small lot of lead-copper ore was shipped crude to a smelter from the Silver Queen mine.

Northport district.—The Sierra Zinc Co. operated throughout 1942 its 60-ton flotation mill, built late in 1941. A total of 12,123 tons of zinc-lead ore was milled, which contained about 0.01 ounce of gold and 0.6 ounce of silver to the ton, 1.59 percent lead, and 7.36 percent zinc. The mill was operated continuously except for short periods during the winter months; these temporary shut-downs were caused for the most part by weather conditions. Minor additions were made to the mill in 1942, and some adjoining property was acquired for a tailings pond and to furnish a sufficient supply of mine timber. A 40-ton flotation mill was constructed in 1942 on the property of the Frisco Standard Co. near Ione. Machinery was installed, and a test run was made on the lead-copper ore. The property was closed late in October after the tests were completed; operations are to be resumed in the spring of 1943. Among other producers in the Northport district in 1942 were the Electric Point, Gladstone Mountain, and Van Stone, all of which shipped crude lead ore direct to a smelter.

Orient district.—The only producer in the Orient district in 1942 was the First Thought Mine Corporation, which treated 3,780 tons of gold ore in its 50-ton cyanide mill. In May, operations were suspended for the duration of the war.

Springdale district.—Operations at the Lucky Boy mine began in June and continued throughout the rest of 1942. During this period, 392 tons of copper ore were treated in the Deer Trail 100-ton flotation mill.

Digitized by Google

WHATCOM COUNTY

Mount Baker district.—Gold ore from the Boundary Red Mountain mine, treated by amalgamation, comprised the output of the Mount Baker district in 1942.

Slate Creek district.—A little gold ore from the property of the Slate Creek Mining Co. was treated by amalgamation and concentration and a sample lot of ore from the Mammoth group was shipped crude to a smelter.

YAKIMA COUNTY

Bumping Lake district.—Some old clean-up of copper ore and mill cleanings was shipped direct to a smelter in 1942 from the property of the Copper Mining Co.

GOLD, SILVER, COPPER, AND LEAD IN WYOMING

(MINE REPORT)

By CHAS. W. HENDERSON

SUMMARY OUTLINE

	Page		Page
Summary	517	Mine production by counties	518
Calculation of value of metal production	517	Review by counties and districts	518

SUMMARY

Lode and placer mines in Wyoming in 1942 yielded—in terms of recovered metals—23 fine ounces of gold, 52 fine ounces of silver, and 6,000 pounds of lead; the total calculated value was $1,244. Of the total metal produced, 12 ounces of gold were recovered from placer mining—the output from six properties in the Atlantic City district, Fremont County.

No large lode-mining operations were carried on in the State to recover gold, silver, copper, or lead in 1942. Six small lode mines, none of which shipped or treated over 25 tons of crude ore, yielded—in terms of recovered metals—11 fine ounces of gold, 52 fine ounces of silver, and 6,000 pounds of lead. Lead ore totaling 25 tons (yielding the bulk of the silver and all the recovered lead produced in the State in 1942) was shipped from the Black Buttes claim in Crook County to the Garfield (Utah) smelter. A total of 59 tons of crude ore was treated in five small amalgamation mills—four in Fremont County and one in Johnson County—which recovered 11 ounces of gold and 1 ounce of silver.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1938–42

Year	Gold [1]	Silver [2]	Copper [3]	Lead [4]	Zinc [4]
	Per fine ounce	*Per fine ounce*	*Per pound*	*Per pound*	*Per pound*
1938	$35.00	[5] $0.646+	$0.098	$0.046	$0.048
1939	35.00	[6] .678+	.104	.047	.052
1940	35.00	[7] .711+	.113	.050	.063
1941	35.00	[7] .711+	.118	.057	.075
1942	35.00	[7] .711+	.121	.067	.093

[1] Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was $20.67+($20.671835) per fine ounce.

[2] Treasury buying price for newly mined silver.

[3] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production but excludes value of foreign copper delivered to Metals Reserve Co. for domestic consumption.

[4] 1938–41: Yearly average weighted price of all grades of primary metal sold by producers; 1942: Price includes bonus payments by Metals Reserve Co. for over-quota production.

[5] $0.64646464.

[6] $0.67878787.

[7] $0.71111111.

Digitized by Google

The following table shows the annual output of ore from lode mines producing gold, silver, copper, and lead and the quantity and value of the metals recovered from both lode and placer mines in Wyoming from 1938 to 1942; it also gives the total production of metals from 1867 to 1942. About three-fourths of the total recorded value of the four metals is in copper, most of which was mined before 1924 in the Encampment district, in Carbon County, and the Hartville district, originally in Laramie County, now in Platte County.

Mine production of gold, silver, copper, and lead in Wyoming, 1938–42, and total, 1867–1942, in terms of recovered metals

Year	Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)		Copper		Lead		Total value
		Fine ounces	Value	Fine ounces	Value	Pounds	Value	Pounds	Value	
1938	581	798	$27,930	328	$212					$28,142
1939	57	583	20,405	75	51					20,456

REVIEW BY COUNTIES AND DISTRICTS

ALBANY COUNTY

Douglas Creek district.—Development and assessment work were the only mining operations carried on in Albany County during 1942. Ira J. Knisley, of Holmes, did assessment work on the Depression No. 1 and 2 placer ground on the west branch of Little Beaver Creek. The Independence Gold Mining Co., Inc., did development work and made tests for the treatment of ore from its Independence group of claims 3½ miles west of Centennial.

CARBON COUNTY

Encampment or Upper Platte district.—Development and assessment work were done on the Golden Clover claim, 15 miles south of Encampment, by the Golden Clover Mining Co.

Digitized by Google

CROOK COUNTY

Hurricane district.—One car of lead ore containing 51 ounces of silver and 6,977 pounds of lead was shipped to the East Helena (Mont.) plant from the Black Buttes claim south of Sundance by L. F. Fletcher of Moorcroft. Two types of ore were mined—a lead carbonate ore and a sulfide ore.

FREMONT COUNTY

Atlantic City district.—Placer mining in the Atlantic City district in 1942 yielded 12 ounces of gold valued at $420. Frank Antich, Atlantic City, operated the Miners Delight placer and treated about 2,400 cubic yards of gravel, from which 7.38 ounces of gold were recovered; the average fineness of the bullion was 0.851 in gold. This was the largest single producer of gold in the State in 1942. No other individual placer operation in the Atlantic City district produced more than 2 fine ounces of gold. Six hundred cubic yards of gravel from the Bonanza placer, yielding 1.52 ounces of gold, were treated by R. A. Swabes of Rock Springs. Joe Barbett, operating the Timba-Bah Mining Co. property about 5 miles below Atlantic City (largest single producer of gold and silver in the State in 1941), produced 1.67 ounces of gold. Individuals sluicing at the Badger-Fox-Coyote, Big Atlantic, and Sweetwater River placers near Atlantic City and South Pass City recovered small lots of placer gold, which were sold to the Smith-Sherlock Co. at South Pass City.

Roy A. Cowden, of Atlantic City, operated the Gold Leaf and Mint lode-mining claims and treated 24 tons of ore in a 5-ton Gibson amalgamation mill, producing 5¼ ounces of gold bullion, which was sold to the Denver Mint. James Cassie did development and assessment work on the Reynolds group of claims southeast of Atlantic City and treated about 20 tons of ore, producing 3½ ounces of gold bullion, which was sold to the Denver Mint. Some development work, consisting of 100 feet of tunnel, was done at the McGrath-Diana mine; the mill equipment and buildings were sold and moved to Ten Sleep, Washakie County, during the summer of 1942.

Copper Mountain district.—Charles Simerson operated the Gold Nugget mine on Copper Mountain; about 3 ounces of gold were produced.

GOSHEN COUNTY

Some development work was done on the old Michigan mine in the Hartville Uplift region, northeast of Sunrise, by Oscar Alexander, of Manville. No shipments were made.

JOHNSON COUNTY

The Powder River Exploration Syndicate treated a few tons of ore from the Powder River mine and shipped 5 ounces of gold bullion to the Denver Mint. The property is in the Big Horn Mountains southwest of Buffalo and was recently purchased by the Empire State Oil Co. of Thermopolis.

Digitized by Google

PARK COUNTY

No metal was produced from Park County in 1942. Charles F. Wolf and associates did some sampling and exploration work on the mining claims in the Kerwin camp, about 50 miles south of Cody.

PLATTE COUNTY

The only mining operations in Platte County in 1942 were those carried on by the Colorado Fuel & Iron Co. at its Sunrise iron mine. No copper ore was produced.

SECONDARY METALS—NONFERROUS

By F. H. WRIGHT[1]

SUMMARY OUTLINE

	Page		Page
General summary	521	Secondary nickel	531
Salient statistics	521	Secondary lead	533
Scope of report	522	Secondary tin	536
Secondary aluminum	522	Detinning plants	538
Secondary magnesium	525	Secondary antimony	539
Secondary copper and brass	526	Secondary zinc	540

GENERAL SUMMARY

Although the nonferrous secondary metals industry was handicapped by a shortage of manpower and by necessary Government restrictions on uses of certain metals, the year 1942 saw several production records broken. The value of the more important nonferrous metals recovered from scrap as unalloyed metal and in alloys and chemicals totaled $425,991,475, compared with $348,377,389 in 1941. Secondary metals recovered from new or byproduct scrap that left the plant of its origin were valued at $229,126,659, and metals reclaimed from old scrap materials were worth $196,864,816.

Salient statistics of nonferrous secondary metals recovered in the United States, 1941–42

Metal	New scrap		Old scrap		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1941						
Aluminum	63,744	$20,704,051	43,113	$14,003,102	106,857	$34,707,153

		229,126,659		196,864,816		425,991,475

Recovery of secondary lead, tin, antimony, and nickel (nonferrous) declined, but reclamation of secondary aluminum, copper, zinc, and magnesium broke all previous records owing to the increased volume of fabricators' scrap that flowed from war plants. The scrap-remelting facilities of primary aluminum producers and brass mills were so

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Digitized by Google

overtaxed that part of the furnace capacity of a number of secondary smelters and refiners was brought into use to melt wrought alloy scrap. Production of secondary brass and aluminum casting alloy ingots was greater than ever before, but unusually large quantities of refined copper, tin, and zinc were required by brass-ingot makers in addition to the scrap used for production of lead-free bronze to meet rigid specifications of the Army and Navy.

SCOPE OF REPORT

The regular annual survey of nonferrous-scrap consumption and secondary-metal production was augmented in 1942 by a monthly canvass of approximately 4,500 scrap-metal dealers, and by separate monthly canvasses of consumers of zinc scrap and white-metal scrap. Annual reports of scrap use were received from 373 plants classed as secondary remelters, smelters, or refiners of one or more nonferrous metals, from 37 brass mills, 27 aluminum rolling mills and fabricators, 48 chemical works, and 1,219 foundries and other manufacturers that consumed purchased nonferrous scrap.

SECONDARY ALUMINUM

The secondary-aluminum industry operated its scrap-melting facilities more nearly at capacity levels in 1942 than in 1941. The quantity of secondary aluminum [2] recovered from scrap (198,492 short tons valued at $58,039,061) was almost double the 1941 output (106,857 short tons valued at $34,707,153). The value was computed at 14.62 cents a pound of aluminum recovered, compared with 16.24 cents a pound in 1941. Production of primary aluminum was 521,106 short tons, and the net total production in the United States consisted of primary production plus recovery from old scrap, or 564,767 tons.

Of the 14,104 tons of secondary aluminum recovered as unalloyed metal, 21 percent appeared on the market as "pure" (98.5 percent) aluminum ingot, 6 percent as aluminum powder, and 73 percent in commercial shapes produced by rolling mills.

Secondary aluminum [1] recovered in the United States, 1941–42, in short tons

Secondary aluminum recovered			Recoverable aluminum-alloy content of scrap		
Form of recovery	1941	1942	Kind of scrap processed	1941	1942
As metal	8,308	14,104	New scrap:		
Aluminum alloys	[3] 96,571	180,979	Aluminum-base [3]	63,726	154,436
In brass and bronze	334	1,268	Copper-base	12	297
In zinc-base alloys	709	473	Zinc-base	6	98
In chemical compounds	935	1,668		63,744	154,831
	106,857	198,492	Old scrap:		
			Aluminum-base [4]	43,049	43,249
			Copper-base	31	213
			Zinc-base	33	199
				43,113	43,661
				106,857	198,492

[1] In accordance with common usage, the term "aluminum" covers aluminum alloys, and the figures include all constituents of the alloys recovered from aluminum-base scrap.
[3] Revised.
[3] Aluminum content of new aluminum-base scrap was 59,097 tons in 1941 and 143,633 tons in 1942.
[4] Aluminum content of old aluminum-base scrap was 39,858 tons in 1941 and 41,221 tons in 1942.

[2] The term "secondary aluminum" is used broadly to cover aluminum and aluminum alloys, including the weight of alloy constituents, such as copper, silicon, magnesium, and others.

Digitized by Google

By far the largest proportion of secondary aluminum (180,979 tons) was recovered in aluminum alloys in the form of ingots, wrought products, and castings. The gross weight of secondary aluminum ingots produced by aluminum smelters was 144,694 short tons, of which 138,741 tons represented alloyed aluminum recovered from scrap, and the remainder represented additions of other raw materials. Secondary aluminum-ingot production represented a 72-percent gain over 1941. Increased steel production and denial of primary aluminum for deoxidation caused production of secondary aluminum steel-mill ingot and shot to increase 59 percent and provided an outlet for secondary aluminum of high iron content.

The extensive use of rolled products for airplanes together with the Government order that made it mandatory for fabricators to sell their segregated 17S, 24S, and 52S alloy scrap in solid form to the Aluminum Co. of America or Reynolds Metals Co. resulted in greater consumption of scrap at the aluminum rolling mills. These plants of primary producers recovered 53,080 tons of aluminum alloys by combining scrap and secondary "process" ingots with primary metals used for wrought products.

After aluminum scrap had been placed under strict control on January 7, 1942, only authorized remelters, smelters, and chemical works were allowed to consume it. Manufacturers and foundries produced only 848 tons of aluminum powder and 480 tons of aluminum alloy castings from scrap, mostly in the first week in January, and thereafter resold 680 tons of the purchased aluminum scrap they had on hand and reported only 205 short tons in inventory at the end of 1942.

In addition to these aluminum-base products, 686 tons of aluminum from aluminum scrap and 582 tons from aluminum bronze scrap were recovered in aluminum and manganese bronze products, and recovery of 176 tons of aluminum from aluminum scrap and 297 tons of aluminum from zinc-base alloy scrap was reported in zinc-base alloy products.

Consumption of 217,611 short tons (gross weight) of purchased aluminum scrap represented an increase of 72 percent over 1941. Approximately 73 percent of the scrap was used by 75 remelters, smelters, and refiners, 26 percent by 27 plants classed as aluminum rolling mills, and 1 percent by 281 foundries and miscellaneous manufacturers. The high rate of activity in fabrication of wrought aluminum for aircraft was reflected in the fact that 80 percent of the scrap consumed in 1942 was new scrap, compared with 64 percent in 1941 and only 43 percent in 1940. The consumption of old aluminum scrap continued on a slight downward trend in 1942, having dropped from 47,572 tons in 1940 to 45,329 tons in 1941 and to 43,248 tons in 1942.

Borings and turnings	77,022		7		894		77,923
Die castings	2	6	10		19	2	39
Miscellaneous aluminum and dross	17,863	1,584			220		19,667
	117,485	42,696	55,621	19	1,257	533	217,611

Dealers in nonferrous scrap metal shipped 100,796 short tons of aluminum scrap to consumers out of the 103,856 tons they collected from domestic and industrial sources during 1942. A general upward trend was noted in the monthly volume of dealers' transactions in aluminum scrap during the last 8 months of 1942 after revisions in Government regulations allowed scrap generators to sell segregated plant scrap to dealers in lots up to 5,000 pounds per month compared with the earlier limitation of 1,000 pounds. Dealers' stocks increased from 5,660 tons on hand January 1 to 8,720 tons December 31, 1942.

Consumers' stocks of purchased aluminum-base scrap in the United States at end of year, 1941–42, gross weight, in short tons

Scrap item	On hand—	
	Dec. 31, 1941	Dec. 31, 1942
Castings and forgings	2,004	1,690
Sheet, turnings, clippings, etc.	6,070	5,020
Miscellaneous aluminum and dross	1,521	1,915
	9,595	8,625

The aluminum industry continued under close Government control throughout 1942. The overwhelming demands of a nation at war for the available supply of aluminum required further restrictive and conservation orders to supplement or replace those already operating at the beginning of 1942. On January 26, 1942, aluminum was limited to 15 uses, most of them restricted to low-grade secondary aluminum containing more than 4 percent copper and either iron or zinc in excess of 1 percent. Aluminum was limited to 2 percent in zinc-base alloys and to a maximum of 15 percent in other alloys on August 18, 1942, but an amendment on November 20 removed all restrictions on the aluminum content of zinc-base alloys. Segregation of aluminum scrap by alloy content and form was made mandatory early in 1942. Every plant generating 1,000 pounds or more of aluminum scrap per month was ordered to segregate scrap at the machine at which it was generated.

Digitized by Google

Formal Government price ceilings established in 1941 were continued throughout 1942. The basing point of aluminum scrap prices was that of No. 1 virgin aluminum ingot, which remained at 15.00 cents a pound delivered. The average selling price of 98 percent pure secondary ingot was also 15 cents. The aluminum price schedule was broadened on August 20 to cover all secondary aluminum ingot and virtually all grades of aluminum scrap. Effective October 16, 1942, an amendment established a maximum price of 1.25 cents a pound for aluminum drosses, skimmings, grindings, etc., containing less than 15 percent by weight of metallic aluminum. Later in the year, toll agreements were exempted from scrap ceilings, and premiums were allowed on briquetted scrap and material properly prepared for briquetting.

Dealers' buying prices for cast aluminum scrap in New York averaged 8.62 cents a pound, compared with 10.76 cents in 1941. The monthly average price dropped from 9.37 cents in December 1941 to 8.73 cents in January 1942, then remained static until October 1942, when the price began to decline to the year-end level of 8.12 cents a pound.

Dealers' buying prices for new aluminum clippings in New York averaged 9.50 cents a pound, compared with 13.00 cents in 1941. The Government order in January requiring the segregation of fabricators' scrap spurred the price of new clippings from an average of 9.59 cents in January 1942 to 9.87 cents in March. Strong smelter demand for this type of graded scrap maintained the high price level through June, but the average price declined to 9.12 cents in September, where it remained for the rest of 1942.

Imports of aluminum scrap totaled 487 short tons, compared with 55 tons in 1941, and exports amounted to only 32 tons, compared with 57 tons in 1941.

SECONDARY MAGNESIUM

Expanded production of magnesium for war uses brought a proportionate increase in the generation of magnesium scrap, and recovery of secondary magnesium from purchased scrap totaled 6,238 short tons valued at $2,794,624, compared with 1,752 tons valued at $840,960 in 1941. The value was computed from the average selling price of all grades of primary magnesium, which was 22.4 cents a pound in 1942 and 24 cents in 1941. Most of the secondary magnesium was recovered in the form of magnesium alloy ingot for subsequent blending with primary magnesium or alloying with aluminum, but small quantities of magnesium scrap were consumed directly in production of aluminum, lead, and zinc alloys, for deoxidation of metals, and as a chemical catalyst in the Grignard reaction.

All but 1 percent of all the secondary magnesium was reclaimed from new scrap generated in manufacturing operations, as not enough magnesium had been used in former years to build up a backlog of obsolete magnesium objects for salvage. Purchased magnesium scrap was consumed in 39 plants representing 27 companies, but 97 percent of the secondary magnesium was recovered in 10 plants of 7 companies. Consumption of magnesium scrap totaled 7,317 short tons, compared with 2,279 tons treated in 1941.

Magnesium alloy castings (gross weight)	738	93
In aluminum alloys	60	46
In lead alloys	(2)	2
In zinc alloys	(2)	1
Consumed in chemical and metallurgical processes	25	51
	1,752	6,238
From new scrap	1,737	6,151
From old scrap	15	87

[1] Includes secondary magnesium incorporated in primary magnesium ingot.
[2] Not available.

Use of magnesium, including scrap, was closely controlled by means of priorities issued to approved users according to Federal regulations in effect February 25, 1942. Magnesium scrap could be sold only to primary producers or to seven approved secondary smelters, unless otherwise authorized, but 1,877 tons of magnesium scrap found its way into scrap dealers' yards in 1942. Some of this scrap was purchased by dealers in the belief that it was aluminum, indicating that the trade had not yet become familiar with magnesium as a metal.

Although segregation of magnesium scrap from other metals was required during 1942, it was not until December 31, 1942, that the regulations were amended to require complete segregation of magnesium scrap according to types of alloy at the scrap source.

Stocks and consumption of magnesium scrap in the United States in 1942, gross weight, in short tons

	On hand—		Consumption during 1942
	Dec. 31, 1941	Dec. 31, 1942	
Cast scrap	15	9	223
Solid wrought scrap	22	8	126
Borings, grindings, drosses, etc.	202	215	6,968
	239	232	7,317

Primary magnesium ingot was quoted at 27 cents a pound at the beginning of 1942, but at the request of the Office of Price Administration producers cut the price early in February to 22.5 cents a pound, and this level was maintained for the remainder of the year. Prices of magnesium scrap and remelt ingot were covered by the General Maximum Price Regulation issued April 28, 1942, which established the ceiling price for each seller at the highest price charged during March 1942. Quotations of these prices were not available for record. Definite prices for magnesium scrap and secondary ingot were not fixed until January 20, 1943. On this date maximum prices were set at 9 cents a pound for segregated borings and turnings, 8 cents for contaminated turnings, and 21.5 cents a pound for Class A remelt magnesium ingot (A. S. T. M. specification B93–41T). Segregated plant scrap solids were exempt from the maximum price regulations.

SECONDARY COPPER AND BRASS

Copper recovered as unalloyed metal and in brass or other alloys reclaimed from purchased [3] scrap totaled 927,755 short tons valued at $218,950,180, compared with 726,396 short tons valued at $171,429,456

[3] The term "purchased scrap" includes scrap worked on toll for another and scrap transferred between plants owned by a single company, but does not include "home" scrap reused in the plant in which it originated.

Digitized by Google

in 1941. The value was computed at 11.8 cents a pound in both years. Copper recovered as a constituent of scrap aluminum, nickel, and tin alloys has been included in the secondary copper statistics since 1939, but separate figures showing the recovery from each of these sources are reported in this chapter for the first time.

Recovery of unalloyed copper from scrap continued to decrease, with 114,647 short tons recovered as metal in 1942, compared with 135,869 tons in 1941 and 170,839 tons in 1940. Secondary copper refined at primary plants dropped another 15 percent in 1942 to 85,143 short tons, the smallest production in 10 years, despite Federal encouragement of copper refining from low-grade brass.

The secondary copper content of brass and bronze reclaimed from purchased scrap rose to 779,062 short tons in 1942, an increase of 36 percent over the 574,267 tons recovered in copper-base alloys during 1941. The secondary copper content of aluminum-base alloy products was more than doubled in 1942, with 13,894 tons of copper reclaimed from scrap in this manner, compared with 5,749 tons in 1941. Unalloyed copper scrap was allocated to both primary and secondary aluminum producers in 1942 in lieu of refined copper for alloying, and the copper contained in aluminum-alloy scrap was also used to advantage in bringing total copper content of aluminum alloy ingots up to specifications.

Almost all of the increase in recovery of secondary copper in 1942 was attributed to new scrap, which rose 60 percent to 500,633 tons of recoverable copper, compared with 313,697 tons of copper in new scrap reprocessed during 1941, whereas recovery of copper from old scrap gained only 3 percent in 1942.

A total of 220,217 tons of copper was reclaimed from unalloyed copper scrap. Relatively little of this emerged in unalloyed metal products, for clean copper scrap was consumed largely in the production of brass and bronze, chemicals, and aluminum alloys.

Secondary copper recovered in the United States, 1941–42, in short tons

Secondary copper recovered			Recoverable copper content of scrap		
Form of recovery	1941	1942	Kind of scrap processed	1941	1942

Analysis and production of secondary copper and copper-alloy products in the United States, 1941–42

Item produced from scrap	Approximate analysis (percent)						Gross weight produced (short tons)	
	Cu	Sn	Pb	Zn	Ni	Al	1941	1942
Refined copper (electrolytic grade)	100						109,368	102,975
Casting copper	99						18,700	7,938
Copper sheet, rod, tubing, etc	99						3,855	724
Copper powder	98						2,493	1,165
Copper castings	98						1,453	1,845
Total unalloyed copper products							135,869	114,647
Brass and bronze ingots:								
Tin bronze	88	10		2			26,343	63,333
Leaded-tin bronze	88	6	1.5	4.5			29,404	59,385
Leaded red brass	85	5	5	5			91,389	98,405
Leaded semired brass	81	3	7	9			30,829	19,323
High-leaded-tin bronze	80	10	10				25,005	26,032
Do	84	6	8	2			8,658	10,329
Do	75	5	20				5,850	5,717
Leaded yellow brass	66	1	3	30			21,518	30,401
High-strength yellow brass	58			39		1	31,676	24,055
Manganese bronze	62			27		5	8,202	44,572
Aluminum bronze	89					10	4,261	10,038
Nickel silver	58	2	7	18	14		941	533
Do	65	4	3	5	22		2,205	579
Gilding metal	95			5			5,231	347
Low brass	80			20			1,129	1,310
Silicon bronze	92			4				1,979
Conductor bronze	94	2	2	2				1,529
Hardeners and special alloys	81						6,380	4,793
Total copper-alloy ingots							299,021	402,660
Brass and bronze sheet, rod, tubing, etc							[1] 308,407	[1] 531,159
Brass and bronze castings							[2] 152,637	[2] 111,631
Copper in chemical products (content)							9,804	17,455

[1] Gross weight of secondary brass and bronze in commercial shapes; included 221,492 tons of copper, 1,200 tons of nickel, 4,166 tons of lead, 236 tons of tin, and 81,313 tons of zinc in 1941, and 370,837 tons of copper, 379 tons of nickel, 5,489 tons of lead, 273 tons of tin, 154,107 tons of zinc, 72 tons of aluminum, and 2 tons of antimony in 1942.

[2] Gross weight of secondary brass and bronze castings; included 123,955 tons of copper, 1,424 tons of nickel, 9,087 tons of lead, 6,986 tons of tin, and 11,185 tons of zinc in 1941; and 95,224 tons of copper, 602 tons of nickel, 7,235 tons of lead, 5,389 tons of tin, and 3,181 tons of zinc in 1942.

Refined copper of electrolytic grade totaling 102,975 tons was produced from purchased scrap at 12 refineries, of which 10 were primary plants. "Casting copper" for foundry use was produced for sale at only 10 plants in 1942, compared with production at 21 plants in 1941.

Secondary brass and bronze ingot production in 1942 totaled 402,660 short tons, an increase of 35 percent over ingot production in 1941, although the number of producing plants dropped from 78 in 1941 to 73 in 1942. This branch of industry comprised 67 concerns in 1942. Counting secondary smelters of aluminum and lead, as well as copper refiners and brass-ingot makers, 112 smelting plants used copper-base scrap.

The types of brass and bronze casting alloys produced to fill wartime requirements in 1942 showed considerable change from 1941. Production of both lead-free and low-leaded tin bronzes more than doubled, and the manufacture of manganese "bronze" was more than 5 times that of 1941, whereas nickel silver virtually disappeared and high-strength yellow brass dropped off.

Producers' stocks of secondary-brass ingots dropped from 14,071 short tons (revised) on hand December 31, 1941, to 13,838 tons on December 31, 1942, and shipments totaled 402,894 short tons.

Digitized by Google

Consumption of purchased copper and copper-alloy scrap increased 30 percent to 1,308,782 short tons (gross weight) in 1942, compared with 1,004,170 tons used in 1941. Purchased scrap processed by brass mills increased 74 percent, and the quantity consumed by ingot makers and refiners rose 20 percent, whereas consumption by all other users, including foundries and chemical works, dropped 20 percent in 1942 compared with 1941.

Consumption of purchased copper scrap in the United States in 1942, gross weight, in short tons

Scrap item	Remelters, smelters, and refiners		Manufacturers and foundries				Total scrap used
			Brass mills		Foundries and other manufacturers		
	New scrap	Old scrap	New scrap	Old scrap	New scrap	Old scrap	
No. 1 wire and heavy	8,077	63,921	5,860	6,244	3,854	22,459	110,415
No. 2 wire, mixed heavy, and light	2,253	87,777	12,771	1,648	1,791	10,077	116,317
Composition or red brass	54,826	81,076			18,677	27,819	182,398
Railroad-car boxes		1,598				30,725	32,323
Yellow brass	21,914	114,808	462,072	12,354	3,476	4,709	619,333
Auto radiators (unsweated)		34,563				423	34,986
Electrotype shells		2,637				287	2,924
Bronze	7,109	5,343	6,285	205	744	1,079	20,765
Nickel silver	107	1,032	1,978			37	3,154

Aluminum bronze	2,459	4,079			2,056	1,169	9,763
High lead brass		464			14	1,997	2,475
Low-grade scrap and residues	87,133	40,593			20		127,746
	186,087	438,978	526,320	20,875	30,988	105,534	1,308,782

Many foundries that had formerly used scrap turned to specification ingot because war orders had to meet the rigid standards of the Army and Navy, and many of the alloys required were different from those used in commercial practice. Scrap requirements of the ingot makers differed from those of former years in that leaded brass scrap could not be used in production of many alloys such as manganese bronze and high-tin bronzes, which were so much in demand, and there was not enough low-lead brass scrap to fill all needs. Unusually large quantities of refined tin and zinc were consumed in production of brass and bronze casting alloy ingots during 1942, and refined copper consumed for this purpose totaled 13,421 tons, compared with 8,226 tons in 1941, although the total unalloyed copper scrap consumed by brass ingot makers and refiners in 1942 dropped only 1 percent from the quantity used in 1941. Fired cartridge cases constituted approximately 6 percent of the total yellow-brass scrap used by ingot makers.

Consumers' stocks of purchased copper-base scrap in the United States at end of year, 1941–42, gross weight, in short tons

Scrap item	On hand—	
	Dec. 31, 1941 [1]	Dec. 31, 1942
Unalloyed copper	15,981	10,019
Copper-base alloy	57,220	87,280
low-grade scrap and residues	34,402	32,647
	107,603	129,946

[1] Revised figures.

Digitized by Google

Consumers' stocks of purchased copper-base scrap rose 21 percent from 107,603 short tons on hand December 31, 1941, to 129,946 tons on hand December 31, 1942. Although stocks rose approximately one-third at both brass mills and smelters, the total copper-base scrap inventory reported by foundries and other manufacturers decreased by one-third.

Maximum prices for brass and bronze alloy ingots were established by written agreement of individual ingot makers with the Government effective February 1, 1942, but official ceiling prices varied in only a few minor details from those previously adhered to on a voluntary basis by ingot producers. Maximum prices were fixed for 85–5–5–5 at 13.50 cents a pound, 88–10–2 at 19.75 cents, and yellow brass at 11.00 cents a pound delivered in carload lots.

On May 18, 1942, the Federated Metals Division of the American Smelting & Refining Co. announced voluntary reductions ranging from one-half to three-quarters cent a pound on many grades of brass ingot, and all other principal manufacturers immediately followed suit.

Formal price ceilings for brass ingots were fixed by Government decree effective August 19, 1942, bringing the average weighted selling prices approximately 1.20 cents below March 1942 levels.

The maximum selling prices for unalloyed copper scrap in effect since October 1941 were continued for the first 4 months of 1942, with No. 1 copper scrap set at 10.00 cents a pound f. o. b. point of shipment. On February 27, 1942, copper alloy scrap was placed under formal ceilings, with prices regulated according to 24 definite grades. The top price for No. 1 red compostion was set at 9.50 cents a pound, and that for yellow-brass cast scrap was 7.25 cents.

Refining of copper from yellow-brass scrap was encouraged by amendments to the brass-scrap price schedule on April 17, 1942. The maximum prices of refinery brass were fixed at 9.25 cents a pound of copper content for material assaying 60.01 percent or more, and 9.00 cents a pound of copper content for material assaying 50.01 to 60.00 percent copper, and the need for sorting the yellow grades sold as refinery brass was eliminated.

Copper-base scrap prices were again revised downward on May 11, 1942, and a license was required for dealers selling to consumers. On August 17, 1942, maximum prices for 13 classifications of copper-alloy scrap were reduced to their proper relationship to the basic 12-cent price of electrolytic copper.

The August 17 scrap ceilings were unchanged during the remainder of 1942, but on December 31, 1942, price ceilings were removed from copper-base scrap imported for the Metals Reserve Co.

Dealers' monthly average buying prices [4] for No. 1 copper scrap at New York held at 9.37 cents a pound throughout 1942, but prices for No. 1 red composition scrap declined continuously from 9.64 cents in January to 8.12 cents averaged in August and September, then rose to 8.87 cents a pound in November and December.

According to new orders issued December 31, 1941, copper-base scrap could be purchased by consumers only under authority of the War Production Board, and controls were exercised to insure the most efficient use of materials available. Unalloyed copper scrap was allocated to replace refined copper wherever possible, and factory

Digitized by Google

segregation of brass mill scrap was made mandatory so that the scrap could be remelted at brass mills for re-use in wrought products. Nevertheless, a substantial quantity of wrought-brass scrap became mixed or contaminated and was eventually consumed by brass ingot makers for casting brasses. Although the refining of copper from yellow-brass scrap was subsidized to some extent by the Government, beginning in April 1942, total production of secondary refined copper was less than in 1941.

Demand was strong for unalloyed copper scrap and high-tin bronze scrap throughout 1942, but the supply of leaded bronze and most grades of yellow brass exceeded demand until September, when consumption of refinery brass for the recovery of refined copper on Metals Reserve Co. accounts appeared to have caught up with the rate of supply in all except the very low grade materials.

A monthly canvass of nonferrous-scrap transactions of scrap-metal dealers was conducted by the Bureau of Mines throughout 1942. Approximately 4,500 dealers, exclusive of peddlers and auto wreckers, were engaged in the trade, and 488,436 short tons (gross weight) of copper and copper-alloy scrap were shipped to consumers during the year. Of the 554,283 tons of scrap received by brass mills from outside sources, only 15 percent, or 85,311 tons, was handled by scrap dealers; but 49 percent of the 812,773 tons of copper-base scrap purchased by all other consumers, including refiners, ingot makers, and foundries, was supplied by the scrap-metal dealers.

Stocks of copper-base scrap in dealers' yards fell from 50,492 short tons on January 1, 1942, to 39,499 tons on February 28, then increased steadily for 10 months to 57,587 tons on hand December 31, 1942.

Brass and copper scrap imported into and exported from the United States, 1941–42, in short tons

	1941	1942
Brass scrap imported	3,596	6,669
Scrap copper imported	2,113	912
Brass scrap exported	722	168
Scrap copper exported	3,259	2,233

SECONDARY NICKEL

Secondary nickel recovered from nonferrous scrap totaled 4,142 short tons valued at $2,899,400, compared with 5,315 tons valued at $3,720,500 in 1941. The value in both years was computed at 35.0 cents a pound, the spot-delivery price of electrolytic nickel, including duty.

Production of secondary Monel-metal pig and shot increased from 289 tons in 1941 to 2,564 tons in 1942, but secondary copper-nickel-shot production dropped from 1,873 tons averaging 48 percent nickel in 1941 to 1,154 tons averaging 40 percent nickel in 1942.

Restrictions on the use of nickel in nonferrous alloys showed their effect in the declines registered in secondary products as well as in decreased consumption of all types of nonferrous nickel-bearing scrap, with the single exception of Monel metal. Total consumption of scrap dropped to 7,908 short tons, of which 60 percent was new scrap and 40 percent was old scrap. Scrap-metal dealers complained

Digitized by Google

during 1942 that there was little outlet for the nickel-silver scrap they had collected, but dealers' shipments of pure nickel scrap and Monel to consumers totaled 3,297 tons.

Secondary nickel (nonferrous) recovered in the United States, 1941–42, in short tons

Secondary nickel recovered			Recoverable nickel content of scrap		
Form of recovery	1941	1942	Kind of scrap processed	1941	1942
As metal	248	90	New scrap:		
In nickel-base alloys	1,267	2,230	Nickel-base	1,904	1,698
In copper-base alloys	3,396	1,470	Copper-base	1,277	732
In cast iron [1]	(2)	114		3,181	2,430
In chemical compounds	404	238			
	5,315	4,142	Old scrap:		
			Nickel-base	1,670	1,373
			Copper-base	464	339
				2,134	1,712
				5,315	4,142

[1] Includes only nonferrous nickel scrap added to cast iron.
[2] Not available.

Consumption of purchased nickel scrap in the United States in 1942, gross weight, in short tons

Scrap item	Remelters, smelters, and refiners		Manufacturers and foundries		Total scrap used
	New scrap	Old scrap	New scrap	Old scrap	
Pure nickel	137	48	64	83	332
Monel metal	2,118	1,243	27	296	3,684
Nickel silver	107	1,032	1,978	37	3,154
Miscellaneous nickel alloys	174	208	48	49	479
Nickel residues			64	195	259
	2,536	2,531	2,181	660	7,908

Priority control over nickel was tightened on April 1, 1942, by an order prohibiting the use of nickel in many items. In the same month, conservation of nickel in waste materials was attempted by means of regulations that ordered segregation of nickel-bearing scrap, both ferrous and nonferrous, as to grades and degrees of nickel content. On October 3, 1942, the use of nickel was restricted to implements of war except under special authorization.

The Government ceiling prices established in 1941 for nickel scrap continued in force throughout 1942. In April, imported nickel-bearing scrap and secondary nickel materials were placed under the maximum selling price regulations, but the Metals Reserve Co. was permitted to purchase manufacturers' unused stocks of metallic nickel without regard to established ceilings. In July, a maximum price of 46 cents a pound for new and 43 cents a pound for partly used nickel anodes was set for Metals Reserve Co. purchases from platers.

Dealers' buying prices for nickel clippings and sheet scrap in New York were quoted at 25 cents a pound until the first week in July, then dropped to 21 cents a pound for the remainder of 1942. Monel clippings were quoted in the New York market at 18 cents for the first 6 months and 16 cents a pound thereafter.

Consumers' stocks of purchased nonferrous nickel scrap[1] in the United States at end of year, 1941–42, gross weight, in short tons

Scrap item	On hand—	
	Dec. 31, 1941	Dec. 31, 1942
Unalloyed nickel	60	65
Nonferrous nickel alloys	3,965	2,282
Nickel residues	485	500
	4,510	2,847

[1] Includes nickel-silver scrap.

No imports of nickel scrap were reported, but exports totaled 4,498 short tons in 1942. Export figures for 1941 were available only for the period July 1 to December 31, and totaled 944 short tons.

SECONDARY LEAD

Secondary lead recovered in all forms in 1942 totaled 323,001 short tons valued at $40,698,126, a drop of 19 percent from recovery in 1941, which totaled 397,416 short tons valued at $45,305,424. Values were computed at 6.3 cents a pound in 1942 and at 5.7 cents a pound in 1941. Production of soft lead, including refined lead, remelt lead, and lead foil totaled 68,870 short tons in 1942, a decrease of 9 percent from the 75,292 short tons produced in 1941. Secondary antimonial lead production decreased 19 percent to 182,839 tons with a lead content of 170,559 tons.

Secondary lead recovered in the United States, 1941–42, in short tons

Secondary lead recovered			Recoverable lead content of scrap		
Form of recovery	1941	1942	Kind of scrap processed	1941	1942
As metal:			New scrap:		
At primary plants	13,454	12,856	Lead-base	9,469	8,509
At other plants	61,810	55,746	Copper-base	7,662	5,844

Composition foil	1,364	1,281	79	4	
Tin content of chemical products	303		303		

The decrease in lead and lead alloys recovered from purchased scrap in 1942 resulted not only from a diminished supply of some types of scrap, but also from Government restrictions on civilian consumption that were designed to conserve lead, tin, and antimony for possible war needs.

Orders that enabled the Government to direct the distribution of lead and tin scrap by allocation were issued on January 8, 1942, and as of January 10, 1942, a conservation order prohibited the use of lead in a definite list of civilian manufactures and curtailed the amount to be used in some of the more essential items. Priority control of secondary lead was incorporated in the regulations on May 18, 1942.

Secondary white-metal smelters were quite active during the first 6 months of 1942, apparently in the belief that lead would be used more widely in war production and as a substitute for scarcer metals. Increased consumer demand failed to materialize, with the result that working funds were tied up in large inventories of finished and semi-processed white-metal alloys, and during July and August many of the secondary lead plants were virtually shut down. When it was found that the lead supply was not as critical as had been anticipated, restrictions were relaxed somewhat beginning November 11, 1942, and were further eased on May 26, 1943.

Of the 276 plants engaged in remelting, smelting, and refining scrap lead and lead alloys during 1942, only 251 produced white-metal products, and the other 25 consumed lead and tin scrap in brass and bronze ingot alloys. A total of 361 manufacturers and foundries con-

Digitized by Google

sumed purchased lead or lead-alloy scrap in their operations but accounted for only a small portion of the secondary metal recovered.

Lead-base scrap consumed in 1942 totaled 396,531 short tons (gross weight), a decrease of 16 percent from the 474,278 short tons processed in 1941.

Consumption of purchased lead scrap in the United States in 1942, gross weight, in short tons

Scrap item	Remelters, smelters, and refiners		Manufacturers and foundries		Total scrap used
	New scrap	Old scrap	New scrap	Old scrap	
Soft lead	80	39,125	219	1,087	40,511
Hard lead		18,323	6	116	18,445
Cable lead		15,074		121	15,195
Battery-lead plates		221,573		9	221,582
Mixed common babbitt		5,923		5,088	11,011
Solder and tinny lead		7,313	4,026	215	11,554
Type metals		20,646		43	20,689
Dross	7,479	42,495	81		50,055
Lead oxide	118	1,064		799	1,981
Residues		5,508			5,508
	7,677	377,044	4,332	7,478	396,531

Manufacturers and foundries treated 3 percent (11,810 short tons) of the total lead-base scrap, whereas remelters, smelters, and refiners handled 97 percent (384,721 short tons). The decrease in consumption of battery-lead plates and hard-lead scrap accounted for more than two-thirds of the total decline in consumption of all lead-base scrap in 1942.

Stocks of purchased lead and lead-alloy scrap held by remelters, smelters, and refiners increased 31 percent, and inventories of manufacturers and foundries gained 1 percent from the beginning to the end of 1942, bringing the over-all increase in total stocks at all plants to 30 percent, from 41,150 tons to 53,460 tons. A similar picture was noted in stocks of scrap lead and tin held by scrap-metal dealers, which gained 28 percent in 1942.

Consumers' stocks of purchased lead-base scrap in the United States at end of year, 1941–42, gross weight, in short tons

Scrap item	On hand—	
	Dec. 31, 1941	Dec. 31, 1942
Unalloyed lead	2,733	5,231
Lead-base alloy	25,642	35,357
Drosses and residues	12,775	12,872
	41,150	53,460

Flow of scrap lead and lead alloys in the scrap metal dealer trade was steady during the first 9 months of 1942 but rose sharply to a peak in October, only to drop back to normal levels in November and December.

On January 15, 1942, price ceilings were imposed on primary lead, secondary lead, and lead-base scrap. Maximum selling prices were set in relation to base prices fixed for each of 146 main shipping points

Digitized by Google

in 34 States. The base price was that of primary pig lead fixed at 6.50 cents a pound, f. o. b. New York, with the ceiling for heavy lead scrap in New York at 5.95 cents a pound. In general, the ceiling prices for scrap lead closely approximated the market prices prevailing at that time.

Dealers' buying prices for heavy lead scrap in New York averaged 5.51 cents a pound in January but rose to 5.62 cents in February and held this level through June. In July the price dropped to 5.39 cents owing to decline in demand. The price fell again in September to a low of 5.37 cents, which continued for the remainder of 1942.

Dealers' quotations for battery plates rose from 3.20 cents to 3.30 cents during January and held steady until May, when the price declined to 3.25 cents a pound. In July the price dropped to a low of 2.87, which was maintained to the end of the year.

Smelting charges for battery lead plates appeared to be nominal in the first half of 1942 but on July 16 were quoted at $24 a ton. In August the figure rose to $25, and this charge was carried through September and October.

Imports of lead scrap totaled 1,305 short tons in 1942, compared with 1,331 short tons in 1941; exports in both years were negligible.

SECONDARY TIN

Secondary tin recovered from scrap in 1942 totaled 37,918 short tons valued at $39,434,720, compared with 42,033 short tons valued at $43,722,726 in 1941. The value was calculated at 52.0 cents a pound in 1942 and at 52.01 cents in 1941.

Tin recovered as unalloyed metal dropped 2 percent, to 5,799 short tons, in 1942, compared with 5,900 tons recovered as metal in 1941; and the secondary-tin content of solder and tin babbitt produced in 1942 was almost halved in comparison with 1941 totals. Secondary tin in chemical compounds produced during 1942 was less than one-third the total reported in 1941, but tin recovered from scrap in lead-base alloy products and in bronze increased 38 and 16 percent, respectively, compared with 1941 figures.

Secondary tin recovered in the United States, 1941–42, in short tons

Secondary tin recovered			Recoverable tin content of scrap

Miscellaneous tin alloys		540			540
	5,086	4,317	34	280	9,717

Supplies of block-tin scrap and high-tin alloy scrap could not keep up with demand in 1942, particularly the need for additional tin in bronze ingots made to Army and Navy specifications. The use of scrap and secondary tin as a substitute for virgin tin was encouraged and was made mandatory in revised Government orders issued January 9, 1943, which stated that no product should be manufactured of pig tin if secondary tin could be substituted.

Secondary lead-tin and lead-tin-antimony alloys such as type metals and lead-base bearing metals were in poor demand throughout the year owing to restrictions on their use, and stocks of these alloys were built up by both scrap dealers and secondary smelters to such an extent that toward the end of 1942 a program was devised for separation of the tin content as refined tin, with the lead and antimony to be recovered as antimonial lead. Purchases of idle stocks of type metals and bearing metals for recovery of tin began in April 1943, with the National Lead Co. acting as agent for the Metals Reserve Co.

Consumers' stocks of purchased tin-base scrap in the United States at end of year, 1941–42, gross weight, in short tons

Scrap item	On hand—	
	Dec. 31, 1941 [1]	Dec. 31, 1942
Unalloyed tin	77	124
Tin-base alloys	431	604
Drosses and residues	1,160	1,199
	1,668	1,927

[1] Revised figures.

Manufacturers' stocks of jewelers' metal, after having been frozen on February 14, 1942, were collected for the account of Metals Reserve Co. and melted into bar tin and tin alloy for allocation as a substitute for primary pig tin. The metal thus recovered was not included in statistics covering scrap or secondary tin, inasmuch as this procedure represented merely a redistribution of metal already measured as part of the total supply.

Beginning April 7, 1942, consumers were required to turn in a used collapsible tube for each new tube of toilet preparations purchased, and the collections were shipped to the Tin Salvage Institute, Newark, N. J. Acting as agent of the Metals Reserve Co., this plant produced its first "tin alloy" pigs in July and by the end of 1942 had reclaimed

Digitized by Google

324 short tons of secondary pig metals containing 231 short tons of tin.

The dealers' buying price for block-tin pipe at New York held steady at 45.50 cents a pound throughout all of 1942, compared with an average of 46.35 cents in 1941. The ceiling prices of 52.00 cents a pound for Grade A pig tin and 51.625 cents for Grade B pig tin that had been fixed in 1941 were continued, and both grades sold at ceiling prices throughout 1942. Although there were no formal maximum prices for tin scrap, selling prices were held in line by virtue of the ceiling on pig tin.

According to orders issued January 8, 1942, the Government was enabled to direct the source, amount, or destination of deliveries of scrap tin and tin-bearing alloys, and scrap dealers' transactions were made dependent on the ratio between scrap shipments and stocks on the basis of a 60-day turnover.

Detinning plants.—The drop in recovery of tin from new tin-plate clippings at detinning plants in 1942 reflected a 16-percent decrease in the quantity of new clippings available; and although the processing of used tin cans brought the total weight of material treated by detinners almost as high as the 1941 figure, total recovery of tin by detinners dropped 9 percent, from 6,156 short tons in 1941 to 5,492 short tons in 1942.

On October 20, 1942, over 400 municipalities in 15 Northeastern States were ordered to collect prepared cans offered in trash collections. Housewives were urged to wash, cut open, and flatten the cans and to keep them in separate containers for collection. The campaign met with indifferent success in many areas owing to the difficulties of collection, lack of transportation facilities, and careless preparation of some of the cans.

Secondary tin recovered at detinning plants in the United States, 1941–42

	1941	1942
Scrap treated:		
Clean tin plate, long tons	341,075	287,660

Average delivered cost of old tin-coated containers, do	(1)	$12.37

[1] Data not available.

In addition to the 7 detinning plants listed in the 1941 edition of this chapter, one other, the Fred L. Hazelquist Manufacturing Co., in Camden, N. J., engaged in detinning activities during the first half of 1942 and recovered tin oxide from old tin cans. Six additional detinning plants, to be located in New York, Buffalo, Birmingham, Chicago, Dallas, and Los Angeles, were planned for Federal construction, but building was halted, after little more than ground-clearing

Digitized by Google

operations had taken place, when it was found that collections of old cans in metropolitan areas could scarcely supply existing facilities. One new shredding plant at Carteret, N. J., was built to prepare "green" cans from the New York area for detinning and was not completed until early in 1943, and three others, at Houston, Kansas City, and Dallas, were constructed to shred cans for copper-precipitation plants.

Imports of tin-plate scrap totaled 24,082 long tons, compared with 22,600 long tons in 1941. Exports of tin-plate scrap, circles, waste-waste, and clippings were only 4,639 long tons in 1942; 14,204 long tons in 1941.

SECONDARY ANTIMONY

Secondary antimony recovered in 1942 totaled 18,200 short tons valued at $5,663,840, compared with 21,629 short tons valued at $6,056,120 in 1941. The value was computed at 15.56 cents a pound, the average selling price for ordinary brands of American-grade antimony in 1942, and at 14.00 cents in 1941.

The 16-percent decline in secondary-antimony recovery in 1942 was attributed to the decreased demand for many of the secondary antimony-bearing alloys usually produced and to reduction in the antimony content of many products (especially battery grids) in accordance with Government orders.

Of the total secondary antimony recovered in 1942, all but 3 tons was recovered from old scrap. Remelters, smelters, and refiners accounted for 96 percent of the total recovery, and manufacturers and foundries salvaged the other 4 percent.

Secondary antimony recovered in the United States, 1941–42, in short tons

Secondary antimony recovered			Recoverable antimony content of scrap		
Form of recovery	1941	1942	Kind of scrap processed	1941	1942
In antimonial lead	15,409	11,943	New scrap:		
In other lead alloys	5,842	6,019	Lead-base	54	(1)

			Tin-base	289	180
				21,572	18,197
				21,629	18,200

[1] Less than 1 ton.

Production of lead-base and tin-base alloy products containing secondary antimony may be found in a table in the section of this chapter relating to secondary lead. Secondary antimony incorporated in lead and tin products totaled 18,154 tons, of which 66 percent was in antimonial lead.

Battery lead plates, the principal source of secondary antimony, provided 56 percent (10,237 tons) of the antimony reclaimed from scrap in 1942, all of which was apparently recovered in antimonial lead products. Other types of lead-alloy scrap, such as lead babbitts, hard lead, cable lead, type metals, and drosses, supplied 43 percent

Digitized by Google

(7,780 tons) and tin-base scrap 1 percent (183 tons) of the total secondary antimony.

Effective January 15, 1942, the maximum price permitted to be charged for the antimony content of antimonial lead was 14.00 cents a pound, but a revision in the price schedule effective April 1 increased the ceiling price to 15.50 cents a pound, and this price remained unchanged for the remainder of 1942.

Government regulations put antimony under full priority control on May 1, 1942. The order prohibited use of antimony in paints, toys, or ornamental objects and limited the quantity of new antimony in automobile batteries to 7 percent of the total used for batteries in any month, with the balance to be obtained from antimony-bearing scrap or secondary alloys. When the supply of antimony became relatively more plentiful toward the middle of 1942, the regulations were liberalized, on July 11, to permit substitution of antimony for tin in bearing metals and other alloys. Effective August 8, 1942, the maximum antimony content of battery grids was raised from 7.5 to 12 percent by weight if only secondary antimonial lead was used in their production.

SECONDARY ZINC

Secondary zinc recovered from purchased scrap and residues totaled 330,526 short tons with a value of $57,511,524 calculated at 8.7 cents a pound, the average selling price for the year of all grades of refined zinc. This represents an increase of 16 percent over the 1941 recovery of 283,967 tons, worth $42,595,050 at an evaluation of 7.5 cents a pound. The figures for recovery include zinc recovered as unalloyed zinc, the zinc content of chemicals, and secondary zinc in aluminum alloys, in brass and bronze, and in zinc-base alloy products.

The over-all gain in secondary zinc was caused by a tremendous expansion in the brass industry, which saw the recovery of zinc in brass from brass scrap rise 61 percent, whereas zinc recovered from zinc-base scrap and residues was 20 percent less in 1942 than in 1941.

Secondary zinc recovered[1] *in the United States, 1941–42, in short tons*

Twenty-seven distillers produced 53,195 tons of redistilled slab having an average zinc content of 99.1 percent, a total exceeded only by the 1941 record high of 59,503 tons. The 18,101 tons of zinc dust manufactured from scrap by 10 distillers in 1942 contributed 80 percent of the total zinc-dust production from all sources but represented a decline of 4 percent from the 1941 figure for dust produced from scrap. The drop in production of both redistilled slab and dust was the result of a shortage in raw materials rather than a smaller demand for the products. Two producers of redistilled slab discontinued operations owing to the difficulty of obtaining enough residue for efficient operation.

Production of secondary zinc and zinc-alloy products in the United States, 1941–42, gross weight, in short tons

Product	1941	1942
Redistilled slab zinc	59,503	53,195
Zinc dust	18,950	18,101
Remelt spelter [1]	10,459	8,637

Consumption of purchased zinc scrap in the United States in 1942, gross weight, in short tons

Scrap item	Remelters, smelters, and refiners		Manufacturers and foundries		Total scrap used
	New scrap	Old scrap	New scrap	Old scrap	
Clippings	3,241		2,398		5,639
Sheet and strip	293	8,183	461	351	9,288
Engravers' plates		1,930		80	2,010
Skimmings and ashes	43,353		21,976		65,329
Dross	47,412		11		47,423
Die castings	670	14,203	135	311	15,319
Flue dust and residues	10,983	783	10,364	13,692	35,822
	105,952	25,090	35,345	14,434	180,830

The auto-wrecking campaign conducted throughout most of 1942 increased the supply of scrap die castings, and Federal regulations of zinc consumption in the printing trade were responsible for the movement of old engravers' plates. Old zinc scrap composed of die castings, engravers' plates, sheet, strip, and flue dust constituted 22 percent of the total zinc scrap consumed in 1942. Metallic scrap was used in making remelt spelter, zinc alloys, brass, and redistilled zinc.

By the end of 1942, galvanizing activity had decreased to 40 percent of what it had been in the comparable portion of 1941. The net result of this diminished activity was a 20-percent decrease in the supply of galvanizers' skimmings and dross and a lower yield of zinc dust and redistilled slab in 1942.

Consumers' stocks of purchased zinc-base scrap in the United States at end of year, 1941–42, gross weight, in short tons

Scrap item	On hand—	
	Dec. 31, 1941	Dec. 31, 1942
Metallic zinc scrap	1,378	2,960
Dross	5,634	4,232
Skimmings and residues	32,433	34,625
	39,445	41,817

The rate of shipment of zinc scrap from nonferrous scrap-metal dealers to consumers increased steadily from the beginning of 1942 until the year's high mark was reached in May, then declined for 4 months before another increase was evident. Zinc scrap handled by dealers consisted for the most part of old metallic scrap, as flue dust and most of the new scrap and residues were shipped directly from generator to consumer.

Virtually no control was exercised over scrap or remelt zinc during 1942, but early in 1943 a general zinc shortage forced the Government to amend refined-zinc regulations to include remelt zinc in the list of completely allocated materials. At the same time the disposition of all zinc scrap was put under control, and delivery of zinc scrap was not permitted to anyone other than a scrap dealer or a manufacturer for use in the production of redistilled zinc, remelt zinc, brass, zinc dust, zinc oxide, chemicals, or salts unless specific authority to do otherwise was first obtained.

Government control kept prices of zinc scrap in line throughout 1942. Scrap dealers' monthly average buying prices for new zinc clips at New York averaged 6.45 cents a pound during 1942 and ranged from a high of 7.00 cents in March and April to a low average of 5.79 cents in September. Corresponding prices for old zinc scrap in the same market averaged 4.65 cents a pound during 1942, with high and low monthly averages of 5.25 cents in March and April and 3.83 cents in September.

Imports of old zinc scrap totaled 143 short tons, compared with 103 tons in 1941. Imports of residues classed as "zinc dross and skimmings" totaled 353 short tons in 1941 but soared to 3,199 tons in 1942 owing to importation of large quantities of fume from a primary zinc smelter in Canada. Zinc recovered from this fume was not counted as secondary zinc.

GENERAL SUMMARY

The continued stimulus of expanding war industries' needs was responsible for a record production of steel ingots in 1942, with consequent greatest demand for iron and steel scrap ever known. The production increased 4 percent over that in 1941. Reflecting this rise, use of purchased ferrous scrap at steel furnaces increased 6 percent over consumption in 1941—the previous record year—although pig-iron production rose 7 percent. During the entire year consumption of scrap remained fairly stable, since steel-ingot production was consistently greater than 95 percent of rated capacity, the use of scrap reaching a peak in October.

Total consumption of ferrous scrap and pig iron was 3 percent greater than that in 1941. Of the 119,308,034 short tons used, 97,598,709 were charged to steel-making furnaces and 20,443,522 to iron furnaces. In making the average ton of steel in 1942, more pig iron and less scrap were used than in 1941; the relative use of home scrap decreased considerably in 1942 from 1941, but that of purchased scrap increased slightly. The relative decline in the use of home scrap undoubtedly was caused by exportation of large quantities of steel ingots and semifinished steel under lend-lease agreements, which removed potential plant scrap from circulation. In iron furnaces, also, the use of pig iron increased relatively and that of scrap decreased.

During the first 3 months of 1942 stocks of iron and steel scrap declined consistently; however, with the advent of warmer weather the movement of scrap became easier, and there was a gradual uptrend in inventories throughout the remainder of the year. The continued high operating rates in steel production during the year occasioned considerable alarm over the position of domestic stocks of iron and steel scrap. However, the monthly surveys conducted by the

[1] Minerals Yearbook, 1939, p. 513, gives definitions of the various scrap terms used in this report.

Digitized by Google

Bureau of Mines revealed that available inventories of scrap were rising above the late 1941 lows. The survey of suppliers', producers', and consumers' stocks at the end of 1942 [2] indicated inventories of 7,803,151 short tons, equivalent to 7 weeks' supply at the December rate of consumption. Consumers' stocks of scrap increased from 3,726,030 tons at the beginning of 1942 to 6,316,138 tons at the close. In contrast with the fluctuation in scrap inventories, pig iron stocks were fairly stable.

Prices for scrap remained at the maximums established by the Office of Price Administration early in 1941. According to Iron Age, the quotation for No. 1 Heavy-Melting steel scrap at Pittsburgh was $20 per gross ton ($17.86 a short ton) throughout the year, compared

Digitized by Google

with $20.34 ($18.16) in 1941. The price of basic pig iron, established at $23.50 per gross ton ($20.98 a short ton) at Valley furnaces in December 1940, prevailed throughout 1942.

Exports of scrap from the United States in 1942 declined 85 percent from 1941 mainly because exports to countries other than the United Kingdom and the Western Hemisphere were placed under Federal control and because shipping facilities were required for finished war materials.

Figure 1 shows the consumption of purchased scrap and the output of pig iron and steel ingots and castings from 1905 to 1942, inclusive.

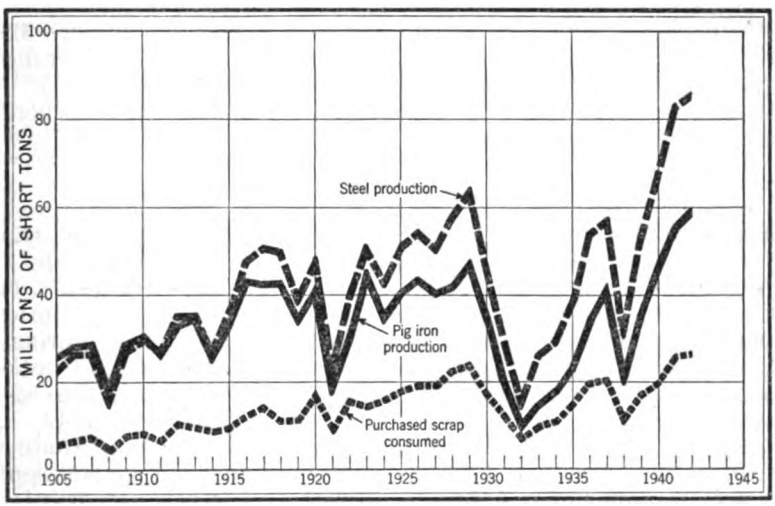

FIGURE 1.—Consumption of purchased scrap and output of pig iron and steel in the United States, 1905–42. Figures on consumption of purchased scrap for 1905–32 are from *State of Minnesota* vs. *Oliver Iron Mining Co. et al.*, Exhibits, vol. 5, 1935, p. 328; those for 1933–34 are estimates by authors; and those for 1935–42 are based upon Bureau of Mines reports. Figures on output of pig iron and steel are as given by the American Iron and Steel Institute.

PRICES [3]

The ceiling prices for scrap fixed by Price Schedule 4 in 1941 remained effective throughout 1942. Market quotations for both No. 1 Heavy-Melting steel and No. 1 Cast cupola scrap were unchanged at $20 per gross ton ($17.86 per short ton) (Pittsburgh).

There were two minor revisions of the basic price schedule in the early part of 1942. These included adjustments in freight and other transportation charges together with the clarification of open-hearth and electric-furnace grades and unprepared scrap. On February 21, 1942, Price Schedule 4 was revised to incorporate all amendments issued after its promulgation on April 3, 1941, and thereafter was entitled Revised Price Schedule 4. Several minor revisions of Revised Price Schedule 4 that appeared during the year included price adjustments on special grades of scrap, addition of new "remote" scrap areas, modification of shipping-point prices, and definitions of No. 1 Heavy-Melting steel and No. 2 Heavy-Melting steel scrap. Gilding metal-clad steel scrap was exempted from price control effective November 16, 1942, by an amendment to the General Maximum Price Regulation.

[3] Pittsburgh price quotations from Iron Age.

Digitized by Google

On May 20, 1942, the Office of Price Administration introduced Supplementary Order 5 licensing every dealer selling to a consumer (and in the case of iron and steel scrap, to a consumer or his broker) any waste, scrap, or salvage materials for which maximum prices are established by price schedules.

The price of basic pig iron, established at $23.50 per gross ton ($20.98 per short ton) at Valley furnaces late in December 1940, remained unchanged throughout 1942.

As the price of scrap exported from the United States was regulated by Revised Price Schedule 4, the price structure remained firm during the entire year. Export-scrap prices in 1942, as indicated by the declared value of iron- and steel-scrap exports, averaged $23.39 per gross ton ($20.89 per short ton) for the year, or approximately 25 percent higher than the 1941 average of $18.74 ($16.73). The 1942 average price was the highest recorded since 1937, when the average was $18.91 ($16.88).

LEGISLATION

Representative Casey's bill (H. R. 5985, 76th Cong.) to suspend the effectiveness of tariff duties on scrap iron, scrap steel, and nonferrous-metal scrap was reintroduced without change as H. R. 6531, 77th Congress.[4] It provided for the suspension of tariff duties or import taxes on scrap metal imported for consumption during the period of unlimited national emergency. After debate in both the Senate and the House of Representatives, the bill was approved and became Public, No. 497, 77th Congress, on March 13, 1942. But on June 1, 1942, the Division of Industry Operations, War Production Board, acting under an Executive Order, issued an amendment to General Imports Order M–63 to restrict the private importation of scrap metals and to provide for purchase of these materials by Government agencies only.

During the year the Division of Industry Operations issued various amendments to General Preference Order M–24. It was made mandatory to segregate tinned and detinned scrap in certain localities, and the sale or shipment of this type of scrap was prohibited outside the areas of origin, except to a detinning plant or copper-precipitation plant; also, an amendment required the segregation of alloy scrap in the entire country. On May 23, 1942, an amendment was issued that removed the inventory restrictions of Priorities Regulation No. 1 and thereby permitted consumers to increase their inventories of iron and steel scrap without limit. The Division of Industry Operations also issued Limitation Order L–88 on May 18, 1943, that restricted the sale as scrap of usable, relaying, and rerolling rails in excess of 10 tons in any calendar month except by permission of the War Production Board.

STOCKS

Available stocks of iron and steel scrap and pig iron in the United States at the end of 1942 were determined by the regular annual canvass of consumers of these materials and the monthly canvass of

[4] H. R. 6531. A bill to suspend the effectiveness, during the existing national emergency, of tariff duties on scrap iron, scrap steel, and nonferrous metal scrap.

Digitized by Google

suppliers and producers. The monthly canvass was expanded to include as producers all manufacturers and railroads that produce 50 gross tons of iron or carbon steel scrap, 10 tons of alloy steel scrap, or 1 ton of high-speed steel scrap in a month. The final results of the annual survey indicate that consumers', suppliers', and producers' stocks of iron and steel scrap totaled 7,803,151 short tons on December 31, 1942, which represents a 59-percent increase over the 4,917,399 tons on hand December 31, 1941.

Consumers' stocks.—Consumers' stocks of home and purchased scrap were considerably larger at the end of 1942 than at the beginning. The supply of 1,605,756 short tons of home scrap on hand on December 31 represented a 38-percent increase over the 1,166,551 tons on hand at the beginning of the year, and the supply of 4,710,382 tons of purchased scrap on hand at the end of 1942 was 84 percent more than the 2,559,479 tons on hand December 31, 1941. Thus, consumers' stocks of scrap totaling 6,316,138 tons at the year end were 70 percent larger than the 3,726,030 tons on hand at the beginning of the year.

Consumers' stocks of pig iron totaled only 1,454,665 tons at the end of the year, a decrease of 8 percent from the 1,585,199 tons on hand at the beginning of the year.

Suppliers' and producers' stocks.—In appraising stocks insofar as suppliers and producers are concerned, it should be noted that the coverage of the canvass is not known precisely. However, the data assembled include virtually complete returns from the larger suppliers and producers, as well as a representative number of returns from others, and the figures shown undoubtedly represent a very substantial part of the total stock of iron and steel scrap in suppliers' and producers' hands.

Stocks held by dealers, automobile wreckers, railroads, and manufacturers increased 25 percent, from 1,191,369 tons on December 31, 1941, to 1,487,013 tons on December 31, 1942. Stocks in the hands of dealers were 37 percent greater at the end of 1942 than at the end of 1941, and manufacturers' inventories gained 20 percent during the same period.

CONSUMPTION

In the canvass of consumers of ferrous scrap and pig iron in 1942, data were assembled on the scrap used in miscellaneous operations, such as rerolling, reforging, and chemical uses, in addition to that used in remelting processes. To simplify the annual canvass, no details are sought regarding the ordinary trade classifications of scrap consumed, and no attempt is made to obtain data on its value or cost at consumers' plants. Statistics are compiled to show the consumption of scrap and pig iron by districts and States and by types of furnace. To avoid disclosing details concerning individual plants reporting, it is necessary in some instances to combine figures for some States. All such combinations are made with a view to revealing details of consumption by types of furnace rather than by geographic subdivisions.

The importance of scrap in the conservation of resources is illustrated by the relative quantities of scrap and ore used in the domestic iron and steel industry. The total scrap consumed in 1942 was equivalent to 114 percent of the iron content of all domestic and foreign iron and manganiferous ores used in blast furnaces, and purchased scrap alone equaled 51 percent of the iron content of the ores; in 1941 the comparable percentages were 123 and 53.

Scrap constitutes by far the greater part of the ferrous raw materials used in iron and steel plants in the Southwestern, Pacific Coast, and New England districts. These regions, however, used less than 6 percent of the total scrap consumed in 1942. In the New England and Rocky Mountain districts (areas that are small producers of pig iron) and the Southwestern district proportionately more scrap was used in 1942 than in 1941; whereas in the remaining districts (Middle Atlantic, Southeastern, North Central, and Pacific Coast) proportionately less scrap was used.

Open-hearth steel furnaces use by far the largest quantities of ferrous scrap and pig iron. They consumed 66 percent of the total scrap in 1942 (67 percent in 1941), 71 percent of the home scrap (71 percent in 1941), 59 percent of the purchased scrap (63 percent in 1941), and 77 percent of the pig iron (76 percent in 1941).

In cupola furnaces, the second-largest consumers of scrap, the relative consumption of home and purchased scrap was changed considerably. They used 12 percent of the home scrap in 1942 (15 percent in 1941), 19 percent of the purchased scrap (22 percent in 1941), and 8 percent of the pig iron (9 percent in 1941).

Open-hearth and cupola furnaces together consumed 83 percent of the home scrap, 78 percent of the purchased scrap, and 85 percent of the pig iron in 1942.

Bessemer converters used 10 percent of the pig iron consumed in 1942 but only relatively small quantities of scrap (0.61 percent of the total). Although electric furnaces consumed only 10 percent of the total scrap in 1942, over 98 percent of the total charge to this type of equipment was home and purchased scrap.

[1] Includes data for 3 Brackelsberg furnaces.

CONSUMPTION BY DISTRICTS AND STATES

All 48 States, the District of Columbia, and Alaska contain plants consuming ferrous scrap and pig iron. The greatest consumption, however, is concentrated in the steel-making centers of the North Central, Middle Atlantic, and Southeastern States. These areas include the 8 largest consuming States, which used 82 percent of the total scrap, 91 percent of the pig iron, and 86 percent of the total scrap and pig iron charged into furnaces in 1942; the comparable percentages in 1941 were 83, 92, and 87, respectively. These States (the relative position of which varied slightly from 1941) and the percentage of the total ferrous scrap and pig iron each consumed in 1942 were as follows: Pennsylvania 28, Ohio 20, Indiana 11, Illinois 9, New York 5, Alabama 5, Michigan 4, and Maryland 4.

The second table following shows total consumption of ferrous scrap and pig iron by districts and percentage change in use of home scrap, purchased scrap, total scrap, and pig iron, 1938 to 1942.

[1] Less than 0.05 percent.
[2] Where 2 or more separate departments, such as blast-furnace, open-hearth, foundry, etc., are situated at the same place and are operated by 1 establishment, each appears as 1 plant in the total.

CONSUMPTION BY TYPE OF FURNACE

Open-hearth furnaces.—Ferrous scrap and pig iron consumed in open hearths in 1942 totaled 85,098,799 tons—a 3-percent increase over 1941. Of the 1942 total, home scrap constituted 27 percent, purchased scrap 19 percent, and pig iron 54 percent. The use of home scrap decreased 2 percent, with the use of purchased scrap and pig iron increasing 1 and 7 percent, respectively.

Digitized by Google

Charges to open-hearth furnaces in 1942 consisted of 46 percent total scrap and 54 percent pig iron, compared with percentages of 48 and 52, respectively, in 1941. Of the total scrap consumed in open hearths in 1942, 41 percent was purchased scrap, compared with 40 percent in 1941 and 41 percent in 1940. Higher proportions of scrap are used in areas remote from pig-iron-producing centers, but the practice of using scrap exclusively is relatively rare. In 1942 only 3 plants out of a total of 145 operated on a 100-percent scrap basis; they consumed only 541,762 tons, less than 1 percent of the total consumption of raw materials in open hearths.

Pennsylvania, the leading steel-producing State, outranked all others in 1942 in the consumption of ferrous scrap and pig iron in open hearths, followed by Ohio, Indiana, and Illinois.

Bessemer converters.—The consumption of ferrous scrap and pig iron in bessemer converters in 1942 totaled 6,501,134 tons—a 2-percent increase over 1941. The proportion of scrap consumed in converter practice is low (amounting to only 5.7 percent in 1942), and the major portion was home scrap. Almost all of the small tonnage of purchased scrap consumed in converters was used in small steel-foundry plants.

Pennsylvania was the principal consumer of scrap in bessemer converters in 1942.

Electric steel furnaces.—Ferrous scrap and pig iron consumed in electric furnaces totaled 5,998,776 tons—a 41-percent increase over 1941. Pig iron constituted less than 2 percent of the total ferrous raw materials used in electric furnaces. Of the 346 active plants reporting, 104 operated exclusively on scrap and consumed 942,678 tons—about 16 percent of the total scrap and pig iron used.

Ohio led all States in 1942 in the consumption of scrap in electric furnaces, followed by Pennsylvania, Illinois, Michigan, and California.

Cupola furnaces.—Consumption of ferrous scrap and pig iron in cupola furnaces totaled 13,545,034 tons—a 15-percent decrease from 1941. Use of home scrap declined 21 percent, purchased scrap 8 percent, total scrap 14 percent, and pig iron 17 percent. Thus, the proportionate decrease in the use of purchased scrap was less than that of pig iron, undoubtedly owing to the establishment of scrap price lower than the price of pig iron.

Charges to cupola furnaces consisted of 29 percent home scrap, 38 percent purchased scrap, and 33 percent pig iron; in 1941 the percentages were 31, 35, and 34, respectively. Many cupola plants operate on a 100-percent scrap charge; 509 plants reported the use of 699,690 tons of ferrous scrap without pig iron in 1942, compared with 511 plants that reported the use of 922,685 tons in 1941.

The relative position of States that are large consumers of scrap in cupola furnaces was altered in 1942 as compared with 1941. Ohio was the principal consumer, followed in order by Michigan, Pennsylvania, Illinois, Alabama, and New York.

[1] Includes some pig iron used in making direct castings.

Air furnaces.—Ferrous scrap and pig iron consumed in air furnaces in 1942 amounted to 1,696,880 tons—a 7-percent decline from 1941. The use of home scrap decreased 5 percent, of purchased scrap 10 percent, and pig iron 8 percent; the use of total scrap decreased 7 percent. Thus, equipment of this type used relatively more pig iron than purchased scrap in 1942. No air-furnace operators reported the exclusive use of scrap in 1942 or 1941.

Ohio led in the consumption of scrap in air furnaces in 1942, followed in order by Illinois, Pennsylvania, Indiana, Michigan, Wisconsin, and New York.

[1] Includes 3 Brackelsberg furnaces—1 each in Indiana, Ohio, and Michigan.

Crucible and puddling furnaces.—Crucible and puddling furnaces, whose combined output of iron and steel is very small, consume only minor quantities of ferrous raw materials.

Blast furnaces.—Ferrous scrap constitutes only a small proportion of the metal-bearing materials consumed in blast furnaces. Other materials used in 1942 were 104,055,422 tons of iron and manganiferous iron ores, 6,368,611 tons of cinder and scale, and 4,177,674 tons of flue dust. Total consumption of scrap in 1942, as reported by 73 plants operating blast furnaces, was 2,937,511 tons, a 1-percent increase over 1941. Of the 1942 total, 53 percent was home scrap and 47 percent purchased scrap.

The proportion of scrap used in blast furnaces decreased in 1942, amounting to 5.0 percent of the pig iron produced, compared with 5.3 percent in 1941 and 4.5 percent in 1940. Purchased scrap was equivalent to 2.3 percent of the pig iron produced in 1942, compared with 2.4 percent in 1941 and 1.7 percent in 1940.

The relative position of the two States that are large consumers of scrap in blast furnaces was reversed in 1942. Pennsylvania became the principal consumer, using 17 percent more than Ohio, the second ranking State; in 1941, Ohio furnaces consumed 8 percent more than Pennsylvania furnaces.

CONSUMPTION IN FERRO-ALLOY PRODUCTION

Data covering the consumption of iron and steel scrap and pig iron in the production of ferro-alloys were assembled for the first time for 1942. The canvass showed that 318,188 tons of ferrous scrap and pig iron were used for this purpose during the year. Various types of furnaces were operated for the manufacture of ferro-alloys, such as blast, electric, and thermic-reduction.

CONSUMPTION IN MISCELLANEOUS USES

As in ferro-alloy uses, data were gathered for the first time for 1942 showing the consumption of iron and steel scrap in such miscellaneous uses as rerolling, copper precipitation, flux in lead blast furnaces, and as a reducing agent in chemical processes. A total of 947,615 tons of ferrous scrap was reported used in these operations during 1942; no pig iron was reported consumed. Illinois was the largest consumer of scrap for miscellaneous purposes, followed by Pennsylvania and New Jersey.

FOREIGN TRADE [5]

Imports.—Imports of iron and steel scrap into the United States, which have never been very significant, totaled 101,337 short tons valued at $1,352,055 in 1942, compared with 71,775 tons valued at $730,844 in 1941. Of the 1942 total, 60,024 tons came from Canada, 19,658 from Cuba, 9,058 from the Panama Canal Zone, 3,959 from Curaçao (N. W. I.), 3,532 from Jamaica, 2,242 from British Guiana, and 2,864 from other countries. In addition, 26,972 short tons of tin-plate scrap were imported during 1942, largely from Canada, compared with 25,312 tons in 1941 and 18,609 tons in 1940.

Exports.—Ferrous scrap exports (all types) from the United States in 1942 totaled only 141,736 short tons valued at $3,321,523. In 1941, 904,249 tons valued at $15,973,863 was exported. The low exportation in 1942 was due to two principal factors. Export licensing established in 1940 restricting exports of all grades of scrap, except to Great Britain and countries of the Western Hemisphere, remained in effect through 1942; also, available shipping facilities were more needed for the transportation of finished war materials. The shipments in 1942 included 5,196 tons of tin-plate circles, waste-waste tin plate, and terne plate clippings valued at $469,458. In 1941, exports of this type of scrap totaled 15,909 tons valued at $1,109,217. The following table shows the principal countries to which scrap was exported during the 5-year period 1938–42.

Ferrous scrap exported from the United States, 1938–42, by countries, in short tons

Country	1938	1939	1940	1941	1942

[1] Figures not yet compiled on annual basis for individual countries.

WORLD ASPECTS

Statistics on the production of steel and pig iron in the world during 1942 are not available, as publication of information has been suspended in many of the countries involved. However, as this is a mechanized war, iron and steel are highly essential to the military and naval forces; therefore, world steel and pig-iron production undoubtedly increased considerably, and the demand for and use of iron and steel scrap was greater than in any previous year.

REVIEW BY COUNTRIES

Canada.—Steel production in Canada reached unprecedented levels in 1942, when the output of steel ingots and castings increased approximately 16 percent over the production in 1941, the previous record

[5] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Digitized by Google

year. Steel ingots and castings produced during 1942 totaled 3,121,000 short tons, whereas production in 1941 amounted to 2,701,000 tons. The increase in Canadian blast-furnace capacity in 1942 was reflected in the record production of pig iron, which showed a larger percentage increment than did steel manufacture. Production of pig iron in 1942 totaled 1,975,000 tons, compared with the previous record of 1,528,000 tons established in 1941, an increase of more than 29 percent.[6] In the record production of steel approximately 1,619,000 tons of pig iron and 1,833,000 tons of scrap were used, resulting in a ratio of 47 percent pig iron to 53 percent scrap, with the scrap charge containing 49 percent home scrap and 51 percent purchased scrap. Slightly more than 130,000 tons of scrap was used in the manufacture of pig iron during 1942. The increased production of steel occasioned alarm as to the scrap supply, but with the large increase in pig-iron production augmented by the scrap obtained from ingots and semifinished steel imported into Canada, these fears were unfounded. Although the production of steel increased, no shortage of scrap occurred, and dealers as well as consumers were able to create stock piles large enough to satisfy requirements for several months in 1943.[7]

At the beginning of 1942, to provide a larger quantity of steel and metals for war industries, the Minister of Munitions and Supply issued orders curtailing the manufacture of civilian materials in which steel or metal was the principal component.[8] At various times throughout the year these restrictions were extended to embrace additional items, including civilian automobiles, refrigerators, other electrical products, and cast-iron and steel pipe.

The maximum price regulations covering scrap established in 1941 were extended to include British Columbia and the Maritime Provinces, placing prices for scrap throughout the entire Dominion of Canada under strict control.[9] In addition, the Steel Controller undertook supervision of distribution of scrap produced by war plants and placed this material under allocation to consuming mills most urgently in need of scrap.[10] Early in the year the government agreed to permit consumers to absorb freight cost in excess of the established maximum prices when the origin of the scrap was remote from the consuming plant; however, they were required to adhere to the ceiling price at the point of purchase.[11] This action tended to stimulate collection of scrap in the western provinces, thereby augmenting supplies near the consuming areas. Former programs to collect scrap were intensified and in the last 6 months of the year were placed under direct control of the government, which provided for a more aggressive salvage campaign on a nationwide basis.[12] The Steel Controller also placed operators of automobile-wrecking yards under strict control, which required them to dispose of all wrecked cars within 90 days from the date the order was issued in March.[13] During August the Department of Munitions and Supply issued an order stating that it would be illegal to retain possession of any scrap metal weighing 500

Digitized by Google

pounds or more after September 15.[14] The order included as scrap any machinery, structural steel, or other article containing iron and steel; it also provided for disposal within 20 days of any scrap metal obtained after the effective date. All these acts increased the flow of scrap material during the year, thereby creating supplies in excess of demands and providing ample inventories at the close of the year. Since exportation of iron and steel scrap from Canada ceased in 1939, except to the United Kingdom and nations of the Western Hemisphere, exports have decreased considerably.

Germany.—Statistics on the production of steel and pig iron and on the consumption of scrap in Germany are not now available. However, as a result of annexation and military occupancy of European countries, steel-ingot capacity is estimated to have been 53,800,000 short tons at the beginning of 1942, or 6 percent greater than it was on January 1, 1941.[15] Nevertheless, steel production has been curtailed considerably by shortages of raw materials and transportation difficulties. The shortage of alloy materials is greatest, which has caused the German steel industry to reduce previously accumulated stock piles of alloying elements.[16] Drives for scrap were intensified, and orders were issued for the confiscation of all unused iron and steel, including finished castings and spare parts.[17] In addition, authorities in charge of war economy established an immense drive in all occupied areas to obtain scrap from sources other than war material.[18]

The German iron and steel industry was organized into one association under the supervision of the Ministry of Economics, with control over the foundries, blast furnaces, and steel works as well as the ore trade and the large iron and steel merchants. This organization was given complete control over the entire industry, including raw materials, production, imports and exports, and prices.[19]

Japan.—Reserve accumulations of scrap held by Japan at the beginning of the year 1942 were estimated at approximately 10,000,000 short tons.[20] The request, made in 1941 by the Ministry of Commerce, that steel-manufacturing companies use a ratio of 70 percent pig iron and 30 percent scrap, had the effect of extending the supply of scrap so that it would last several years should ingot production be maintained at the full capacity of 7,200,000 tons each year.[21] To augment the scrap supply, the Government extended salvage operations previously inaugurated by recovering sunken ships from Japanese waters and by investigation and exploitation of all possible sources.[22] All raw materials were placed under better control, with pig-iron sales being centralized through a separate organization that would purchase the entire output of the principal producers and then sell it to steel mills and foundries at a uniform price.[23]

United Kingdom.—Scrap became a more significant factor in the manufacture of steel in the United Kingdom in 1942, especially since production facilities were expanded and operations increased to a degree never before attained. Imports of scrap from the United

States had been discontinued in September 1941, thereby disturbing normal operations; however, this was partly counteracted by the varying amounts of scrap obtainable from ingots and semifinished material imported under lend-lease agreements. As nearly all the scrap contained in buildings damaged by bombs had been salvaged in 1941, the Ministry of Works and Buildings undertook intensive nationwide drives for iron and steel scrap from other sources, including homes, farms, commercial premises, derelict properties, disused machinery, and pithead equipment.[24] The control of Iron and Steel (Scrap) Order 14, which was issued in 1941 by the British Ministry of Supply to completely control all buying and selling of scrap, was amended to provide higher prices for high-speed steel scrap and magnet scrap.[25] The Ministry of Works and Buildings issued an order designed to compel any person having more than 3 tons of scrap in his possession to sell it if required, thus making it possible to enforce compulsory liquidation of all substantial quantities of this essential raw material.[26] Since transportation difficulties were anticipated and also to compensate for the lack of imports, a series of dumps throughout the country was established to provide a reserve supply of scrap.[27] Also, issued by the Ministry of Works and Buildings was an order making the disclosure of scrap metal compulsory in Great Britain. Under this order, any metal that forms part of any unused, obsolete, or redundant building, structure, plant, or article is considered to be scrap.[28] In the meantime, the voluntary salvage drives underway yielded approximately 1,400,000 tons in 14 months.

GENERAL FEATURES IN 1942

Steel-industry production figures continued upward in 1942. Steel-making capacity increased 2 percent, while production of steel ingots and castings increased 4 percent and totaled 86,031,931 short tons—an all-time high. Pig-iron production totaled 59,077,593 tons, and usable iron-ore output (exclusive of ore containing 5 percent or more manganese) was 118,189,336 tons—both all-time records.

[1] Includes a small quantity of ore from southern Wisconsin. [2] Data not available.
[3] Some underground included with open pit in 1941. [4] Undetermined—not included in total.
[5] Exclusive of ore for paint in 1941.

Digitized by Google

Most of the normal steel-consuming industries received less steel in 1942 than in 1941, owing to the very heavy demands for steel by industries engaged in direct war production. The automobile industry, normally the largest single consumer, ceased producing passenger cars in March, and output totaled only 206,274 units, compared with nearly 5 million in 1941; it was the largest industry to convert to war production. Shipbuilding activity increased phenomenally in 1942; deliveries of steel for shipbuilding soared from less than 3 million tons in 1941 to 9,425,000 tons in 1942. Miscellaneous industries and exports (which include arms production and Lend-Lease consignments) received the largest share (24.6 percent)

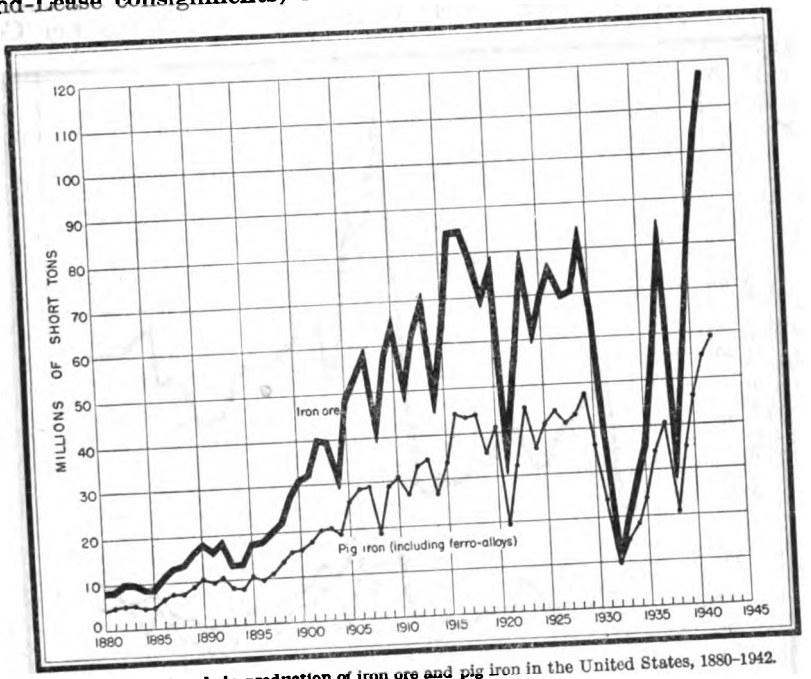

FIGURE 1.—Trends in production of iron ore and pig iron in the United States, 1880–1942.

of steel shipments in 1942, and a slight increase in shipments to the construction industry was apparent during the year.

The annual steel-making capacity of the United States increased to a total of 90,293,000 tons of steel ingots and castings as of January 1, 1943, or 1,723,000 tons above the previous high level of 88,570,000 tons on January 1, 1942. Blast-furnace capacity increased from 60,394,000 tons on January 1, 1942, to 63,302,000 tons at the opening of 1943. The present expansion program for pig-iron- and steel-making capacity will be completed about January 1, 1944. At the completion of the program the United States will have the capacity to produce 97,340,000 tons of steel ingots and castings and 70,881,000 tons of pig iron.

During 1942 the most important development in Government regulation of the flow of steel for war production was the establishment of the Controlled Materials Plan, known as CMP. This plan, effective in the first quarter of 1943, is designed to maintain maximum

Digitized by Google

production of war products and essential civilian products within the limits of available materials and facilities. Its sponsors claimed that it established quantitative controls for a direct balancing of the demand for products with the supply of materials and facilities available for their production.

A drop in employment was felt in the steel industry during 1942. The average number of men engaged in the industry (blast furnaces, steel works, and rolling mills) declined from 543,000 in December 1941 to 520,000 in December 1942. However, employment reached a maximum in June 1942, with a total of 549,000 employees. The average earnings per week in 1942 increased from $39.26 in January to $45.15 in December. Early in 1943, the War Manpower Com-

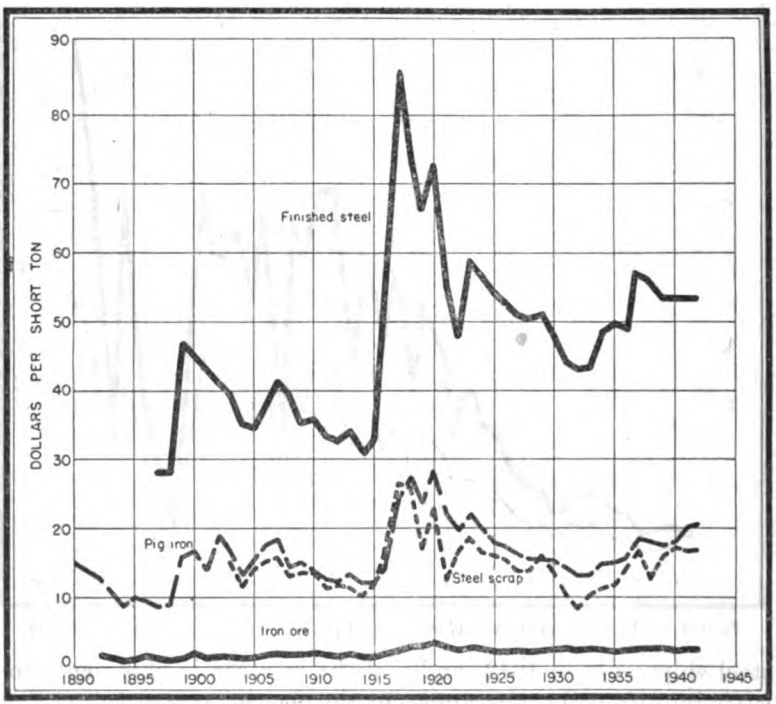

FIGURE 2.—Trends in prices of iron ore, pig iron, finished steel, and steel scrap, 1890–1942. The prices of iron ore and pig iron are the averages, f. o. b. mines and furnaces, respectively, as reported to the Bureau of Mines; the price of finished steel is an average composite computed by American Metal Market; that of steel scrap is an average at Pittsburgh of No. 1 Heavy Melting, computed by Iron Age.

mission gave notice to the steel industry that unless mills are operating on a 48-hour week after July 1, 1943, no additional workers shall be hired for work therein without the approval of the War Manpower Commission. This order in effect will make a 48-hour work week mandatory. It is estimated that because of time-and-a-half pay for work over 40 hours, total wages will increase about 100 million dollars a year. However, about 50,000 fewer employees will be required under this program.

In July 1942 the National War Labor Board granted 157,000 employees of four steel companies (Bethlehem Steel Corporation, Inland Steel Co., Republic Steel Corporation, and Youngstown Sheet

Digitized by Google

& Tube Co.) an increase in wages of 5½ cents per hour. This action brought about adoption of the Little Steel Formula, designed to guide the settlement of wage disputes in other industries. The program provides for a 15-percent increase from the wage level of January 1, 1941. Dr. George W. Taylor, representing the public on the Board, in reviewing the program gave the following principle as a guide in evaluating claims for wage increases [2]:

For the period from January 1, 1941, to May 1942, which followed a long period of relative stability, the cost of living increased by about 15 percent. If any group of workers averaged less than a 15-percent increase, the hourly wage rate during, or immediately preceding, or following this period, their established peacetime standard has been broken. If any group of workers averaged a 15-percent wage increase or more, their established peacetime standard has been preserved.

This formula eventually affected almost every wage earner in the steel industry and most salaried workers as well, with increases retroactive to February 1942. Application of the formula led to wage advances in the automobile industry, whose case was then pending, and to increases in other industries.

IRON ORE

PRODUCTION AND SHIPMENTS

The enormous demand for iron ore by a wartime steel industry resulted in a record year in domestic iron mining. United States iron mines produced 141,710,416 short tons of crude ore during 1942, and shipments totaled 142,010,365 tons. Of this latter quantity, 49,936,613 tons were shipped to beneficiation plants and 92,073,752 tons direct to consumers. A total of 25,917,959 tons of beneficiated ore were produced at milling plants, in addition to 720,172 short tons of byproduct cinder and sinter from the pyrite industry. In all, 118,189,336 short tons of usable ore were produced in 1942. Output in 1942 came from 252 mines, of which 35 mined over 1,000,000 tons of crude ore each. Minnesota, with 82,809,939 tons, supplied 70 percent of the usable ore, and Michigan, with 17,499,060 tons or 15 percent, was the second-largest producer. These two States and Wisconsin (1,682,897 tons or 1 percent) constitute the Lake Superior region, which supplied 86 percent of the domestic output. About three-fourths of the iron ore mined in 1942 came from open-pit mines.

Shipments of usable ore from mines totaled 118,707,133 short tons in 1942. Of this quantity, 91,972,925 tons or 77 percent was direct shipping ore for iron and steel furnaces. Total shipments also include 74,036 tons for cement manufacture, 29,424 tons for paint, and 34,842 tons for miscellaneous uses. Shipments and values of byproduct ore for iron- and steel-furnace use are included for the first time in 1942. These shipments totaled 755,844 tons in 1942 valued at $3,237,511.

PRINCIPAL MINES

The size of a mine is determined by the quantity of crude ore excavated. Hence, mines producing low-grade ores, which require concentration, will be comparable in size to mines producing direct shipping ores. A total of 35 mines, yielding more than 1,000,000

Digitized by Google

short tons of crude ore each, produced 62 percent of the entire output in 1942. Of these producers, 25 were in Minnesota, 4 were in Alabama, 2 in New York, and 1 each in Michigan, Pennsylvania, Wisconsin, and Wyoming; 22 were open-pit operations, 9 were underground operations, and 4 were combination mines. Except for 3 mines that produced magnetite, all the million-ton mines produced hematite.

BENEFICIATION

Iron ore is concentrated by washing, jigging, and magnetic and high-density separation to remove objectionable impurities, thereby improving the grade of the ore. Fine ores are agglomerated or sintered into lumps, which are desirable in blast and steel furnaces because of their porous character and their improved grade and structure. Sintering likewise has the beneficial effect of reducing the sulfur and moisture content. At many mines the ore is crushed and screened to improve its physical characteristics, but ore known to be so improved is not included in the statistics on beneficiated ore.

In 1942 a total of 25,917,959 short tons of beneficiated ore was produced from 49,936,613 tons of crude ore. Beneficiation of iron ore was reported at 120 miles in 9 States in 1942, compared with 112 mines in 8 States in 1941. Beneficiated ore shipped from domestic mines in 1942 increased 21 percent over 1941; concentrates comprised 19 percent and sinter 3 percent of total usable ore shipments.

Beneficiation of crude iron ore in the Lake Superior district (all in Minnesota) began in 1907, when 10,994 short tons of concentrates were shipped from the experimental washing plant of the Oliver Iron Mining Co. on the Mesabi range.[3] From that date, the construction of additional washing, drying, jigging, magnetic concentrating, sintering, and high-density plants in Minnesota increased the proportion of beneficiated-ore shipments to total shipments from 0.03 percent in 1907 to 24 percent in 1942. The quantity of crude ore beneficiated in 1942 totaled 33,142,184 short tons and the beneficiated ore recovered 19,538,752 tons—a ratio of 1.696:1. In 1941 the crude ore treated totaled 28,774,481 short tons and the beneficiated ore recovered therefrom 16,940,412 tons—a ratio of 1.699:1. During 1942, E. W. Davis,[4] Mines Experimental Station, University of Minnesota, and G. W. Hewitt,[5] Wheeling Steel Corporation, urged the construction of additional concentrating plants to beneficiate the magnetic taconite ore at the eastern end of the Mesabi range, to conserve the reserves of Mesabi open-pit direct shipping ores. Davis states that the magnetic taconite may be treated by a process similar to that now in use by the Republic Steel Corporation in New York State. The process consists of crushing the crude ore to a fine size, extracting the iron oxide from it magnetically, and then agglomerating the concentrate. The sintered taconite concentrate would average 62 to 65 percent iron.

The Universal-Atlas Portland Cement Co., Universal, Pa., and the Buffalo Sintering Corporation, Buffalo, N. Y., beneficiated Lake ores. The nodulized ore produced at Universal was used for charge ore in the open hearth, and the sinter produced at Buffalo was consumed in both blast and open-hearth furnaces. Production from these plants is not included in usable ore statistics, as the tonnage has been accounted for in mine shipments.

[1] Includes ore for paint in 1942.

AVERAGE VALUE

The average value per short ton of usable iron ore at the mine was $2.35 in 1942, compared with $2.40 in 1941.

The accompanying table gives the average value at the mines of the different classes of iron ore in 1942 for each of the producing States or groups of States, except when there are fewer than three shippers of a certain class of ore in a State and permission was not given to publish the value. These data are taken directly from statements of producers and probably represent the commercial selling prices only approximately, as not all reports are comparable. Some evidently include mining costs only; others contain, in addition, the cost of selling and insuring the ore; others include an allowance for a sinking fund; and still others comprise only costs charged against blast furnaces. None of the reports, however, is supposed to include freight charges.

Average value per short ton of usable iron ore at mines in the United States in 1942

CONSUMPTION

The production of 59,077,593 short tons of pig iron in 1942 required 104,055,422 tons of iron ore and manganiferous iron ore, 6,368,611 tons of mill cinder and roll scale, and 1,372,599 tons of purchased scrap, an average of 1.892 tons of metalliferous materials (exclusive of home scrap and flue dust) per ton of pig iron made.

Most of the iron ore used in Alabama furnaces in 1942 was hematite from mines in Jefferson County, but small quantities of hematite from Cherokee and Etowah Counties and Walker County, Ga., were also employed. In addition, brown ore, iron sinter, pyrite ash, imported ore, and manganese-bearing ores were consumed. The brown ore originated chiefly in mines of the Birmingham and Russellville districts, Ala., and the Chattanooga district, Ga. The manganese-bearing ores came from Arkansas, Georgia, Tennessee, Virginia, and Cuba. Because of the low-grade ore used in Alabama, the furnaces in this State use more ore per ton of pig iron than any other district in the United States. During 1942 Alabama furnaces consumed an average of 2.537 tons of metalliferous materials per ton of pig produced.

Iron ore and other metallic materials consumed and pig iron produced in 1942, by States, in short tons

	Metalliferous materials consumed				Pig iron produced	Materials consumed per ton of pig iron made

	103,154,498	900,924	7,741,210	111,796,632	59,077,593	1.761	.131	1.892

[1] Includes California, Colorado, Massachusetts, Tennessee, and Utah.

Maryland furnaces consumed chiefly domestic ore in 1942, in addition to ores from Africa, Brazil, Chile, Cuba, and India. These furnaces used an average of 1.661 tons of ore per ton of pig iron; however, they consumed proportionately more cinder, scale, and scrap than those in any other State.

Blast furnaces in Illinois, Indiana, Kentucky, Michigan, Minnesota, and West Virginia handled Lake Superior iron ore and manganiferous iron ore almost exclusively. Kentucky furnaces had the lowest consumption of metal-bearing material per ton of iron.

In New York the furnaces in the Buffalo district used ore chiefly from the Lake Superior district, magnetite from New York, and some manganese ore from Cuba, and the furnace at Troy consumed magnetite from the Chateaugay mine at Lyon Mountain, N. Y.

Digitized by Google

Blast furnaces in Ohio consumed magnetite from New York in addition to ore from the Lake Superior district.

Virtually all the ore consumed in western Pennsylvania furnaces came from the Lake Superior district. Those in the eastern part of the State used some Lake ore; magnetite ores from Pennsylvania, New Jersey, and New York; and some ore from Africa, Australia, Chile, Cuba, and Sweden.

The Pueblo (Colo.) blast furnaces consumed hematite from the Sunrise mine in Wyoming, hematite and magnetite from New Mexico, and manganese-bearing ores, chiefly from Colorado, New Mexico, and California.

The Provo (Utah) furnace treated semialtered magnetite from the Iron Mountain mine near Cedar City, Utah, manganese tailings from Montana, and manganese-bearing ores from Nevada, Texas, and Utah.

Foreign iron and manganiferous iron ore consumed in the manufacture of pig iron in the United States, 1941–42, by sources of ore, in short tons

Source	1941	1942	Source	1941	1942

STOCKS AT MINES

Stocks of usable iron ore at mines totaled 3,770,869 tons at the end of 1942. In addition, 594,751 tons of pyrite cinder and sinter were in stock at plants that produce these byproducts for consumption in iron and steel furnaces. About 90 percent of United States mine stocks were in Michigan and Minnesota.

Stocks of usable iron ore at mines, December 31, 1941–42, by States, in short tons

State	1941	1942	State	1941	1942
Alabama	32,136	33,048	New York	30,947	61,977
Connecticut	67	----	Pennsylvania	90,733	14,354
California	----	2,500	Texas	7,683	6,615
Georgia	----	168	Utah	560	1,344
Michigan	2,172,192	1,909,968	Virginia	3,456	4,379
Minnesota	1,467,745	1,493,331	Wisconsin	213,127	184,144
Missouri	2,790	1,620			
New Jersey	1,761	57,421		4,023,197	3,770,869

STOCKS AT CONSUMING PLANTS

Stocks of iron ore at consuming plants totaled 45,658,562 short tons on December 31, 1942, compared with 40,509,863 tons on December 31, 1941. This large increase was made possible by a favorable shipping season, which enabled shipments to exceed demand. Despite the late opening of the 1943 shipping season, it is believed that stocks at consuming plants at the end of the year will suffice to meet demands until the opening of the 1944 shipping season.

Digitized by Google

FOREIGN TRADE

Imports of iron ore in 1942 decreased tremendously from 1941 owing to the crucial shipping problem. Because of enemy submarine activity, shipments from Chile, which had long been the largest supplier of foreign ore, were suspended in 1942.

Iron ore imported for consumption in the United States, 1940–42, by countries, in short tons

Country	1940		1941		1942

[1] Includes pyrite cinder.

Exports of iron ore from the United States totaled 2,817,235 short tons valued at $8,114,586 ($2.88 a ton) in 1942 compared with 2,136,525 tons valued at $6,212,308 ($2.91 a ton) in 1941.

MINING IN CUBA

Because of war-shipping limitations, shipments from Cuban mines in 1942 were only 9 percent of those made in 1941. The 1942 total of 20,208 short tons included 4,575 tons from the Daiquiri-Juragua mines, averaging (dried) 56.12 percent iron; 2,371 tons from the Estancia mine, averaging (dried) 27.35 percent iron; and 13,262 tons of nodulized brown ore from the Mayari mine, averaging (dried) 56.83 percent iron. The Mayari mine was idle during October, and the Estancia was active only the first 4 months of the year.

Stocks of usable ore totaled 228,071 short tons at the end of the year compared with 101,842 tons at the end of 1941.

Iron ore shipped from mines in the Province of Oriente, Cuba, 1884–1942, in short tons

Year	Juragua, Daiquiri, and Estancia (hematite and magnetite)	Sigua (hematite)	Mayari (brown ore)	Guamá (hematite)	El Cuero (hematite)	Total

REVIEW OF LAKE SUPERIOR DISTRICT

Production and shipments.—The largest movement of iron ore in the history of Great Lakes shipping signalized 1942. A total of 102,596,379 tons of iron and manganese-bearing ores was moved from United States ports during the year compared with the previous record shipments of 89,213,359 tons in 1941 and 72,502,302 tons in 1916. For the first time in the history of Lake Superior commerce, iron ore was shipped in March. . On March 25, 1942, the first uplake boat arrived at Marquette, Mich., and on March 26 another boat reached Duluth. A total of 887,665 tons of ore was shipped in March and 8,723,884 tons in April. Lake shipments reached a monthly record in July, when they totaled 14,933,801 tons. The lakes remained open long enough to permit the movement of 712,128 tons in December. All-rail shipments from the Lake Superior district in 1942 totaled 1,563,490 tons.

A new all-time output of ore from the iron ranges in the Lake Superior district was made in 1942. Production of crude iron ore in the Lake Superior district amounted to 115,773,591 tons, a 16-percent increase over the 99,921,135 tons mined in 1941. Usable iron ore produced in the Lake Superior district, comprising direct shipping ore, concentrates, and sinter, totaled 101,925,624 tons, an increase of 15 percent over 1941. The Lake Superior district supplied 82 percent of the United States crude ore and 86 percent of the usable ore in 1942.

Of the six ranges contributing to the district total, the Mesabi was the largest producer, supplying 77 percent of the Lake Superior total and 67 percent of the United States total of usable ore in 1942.

Usable iron ore produced in the Lake Superior district, 1854–1942, by ranges, in short tons

Shipments from the Michipicoten range in Ontario, Canada, were made to the lower Lake ports for consumption by the Canadian iron and steel industry. This output is not included in Bureau of Mines statistics. Shipments of sinter from the Helen mine of the Algoma Steel Corporation totaled 545,066 short tons in 1942 compared with 518,277 tons in 1941. There was much interest during the year concerning the iron-ore deposits at Steep Rock Lake, in the Lake Superior region, Ontario, Canada. Diamond and churn drilling during 1942 developed indicated reserves of 14,377,000 tons, in addition to 1,525,000 tons of measured Bessemer-grade hematite having an analysis of 62.55 percent iron and 0.17 phosphorus. To exploit the deposit, it will be necessary to divert waters flowing into the lake and build dams so that water covering the deposit can be pumped out. The upper part of the deposit will be mined by an open-cut; however, most of the ore will be mined by underground methods.

Analyses.—The accompanying table was compiled by the Lake Superior Iron Ore Association.

Average analyses of total tonnages (bill-of-lading weights) of all grades of iron ore from all ranges of Lake Superior district, 1938–42

Year	Short tons	Iron (natural)	Phosphorus	Silica	Manganese	Moisture
		Percent	*Percent*	*Percent*	*Percent*	*Percent*
1938	21,675,917	51.90	0.089	8.25	0.81	10.13
1939	50,381,804	51.75	.085	8.27	.76	10.73
1940	70,905,423	52.09	.085	8.00	.77	10.93
1941	89,534,189	51.83	.085	8.18	.78	11.01
1942	103,118,290	51.65	.089	8.21	.79	10.98

Stocks at Lake Erie ports.—On December 1, 1942, just before navigation stopped, the Lake Superior Iron Ore Association reported 8,009,612 short tons of iron ore at Lake Erie ports, compared with 5,924,931 tons on the same date in 1941. At the opening of the 1943 shipping season in May 1943, 3,152,789 short tons of ore were in stock at these ports, compared with 2,832,676 tons on May 1, 1942. Withdrawals from stocks during this 5-month period in 1942–43 were 57 percent greater than in 1941–42.

Prices of Lake Superior ore.—The prices established April 17, 1940, for the four standard grades of Lake Superior ore remained unchanged. Since that date the price of the various grades quoted at Lake Erie ports for a short-ton unit were as follows: Old-Range Bessemer, 8.235 cents; Mesabi Bessemer, 7.975 cents; Old-Range Nonbessemer, 7.975 cents; and Mesabi Nonbessemer, 7.715 cents; respectively, $4.24, $4.11, $4.11, and $3.97 a short ton. The base of the four standard grades for 1925–42 is an iron content of 51.5 percent natural. For the bessemer grades, the allowable phosphorus content is 0.045 percent (dry), and for the nonbessemer grades the phosphorus content ranges from 0.045 to 0.18 percent. Ores containing more than 0.18 percent phosphorus are classed as high-phosphorus ores, whereas those containing 18 percent or more silica are classed as siliceous ores.

Reserves.—During 1942 there was considerable discussion concerning the possible depletion of high-grade iron-ore reserves on the Mesabi range. War requirements will amount to 100,000,000 tons of iron ore to be provided annually by the Lake Superior district. As produc-

Digitized by Google

tion from underground mines and concentrating plants is limited, most of the output must be supplied by open-pit direct shipping ore.

Davis [6] has pointed out that where a deposit of iron ore is flat-lying and is not covered by too much overburden, it is ordinarily mined by open-pit methods; and simply by putting additional shovels into operation and providing the necessary additional transportation, production from open-pit mines can often be doubled or tripled, whereas increasing the production from underground mines is not nearly so simple. The rate of production from an underground mine depends largely on the number of mining faces that can be worked simultaneously, and the maximum rate at which the ore is to be mined is established before an underground mine is opened. Consequently, it is not ordinarily possible to increase the rate of production radically.

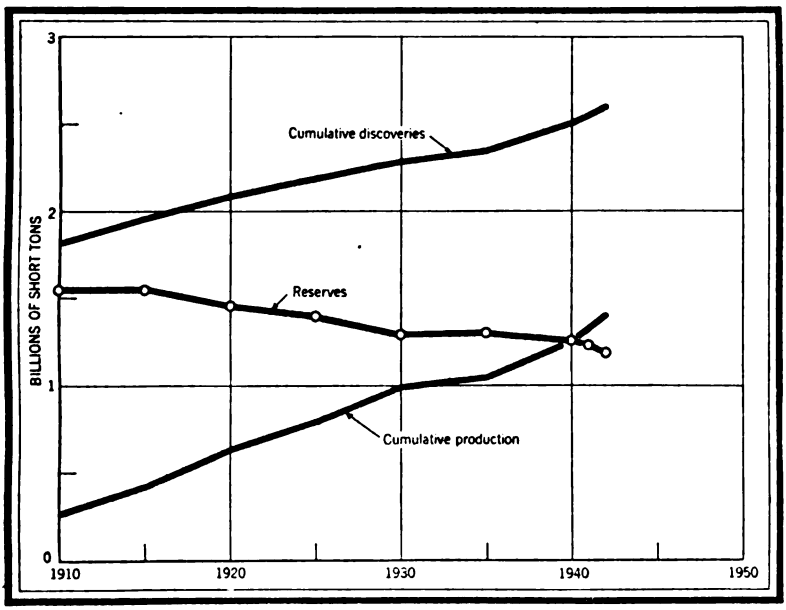

FIGURE 3.—Rates of production, discoveries, and depletion of reserves, Mesabi range, 1910–42.

Actual reserves of the Lake Superior district are not given in the reports of the tax commissions of the various States. Although these commissions have access to all records of the mining companies and compile figures on reserves for the different ranges from them, the figures represent taxable reserves, and the actual tonnages that will eventually be produced from the Lake Superior district will exceed the tax commission estimates. Past records indicate that this excess may be considerable. Figure 3 compares cumulative production and discoveries with reserves on the Mesabi range from 1910 to 1942. During this period, 1.15 billion tons of iron ore were mined. However, this depletion was offset in large part by additions to reserves totaling 0.80 billion tons, so that known reserves decreased only 0.35 billion tons. At current rates of production, it is evident that the known reserves will be exhausted in a relatively short period. Although addi-

[6] Work cited in footnote 3.

Digitized by Google

tions to reserves during the past 3 decades have offset depletion to a large extent, continuation of this trend into the future will depend on the ability of producers to find additional ore and the extent to which present low- and off-grade deposits become commercial in the future.

Unmined iron-ore reserves in Minnesota, May 1, 1938–42, in short tons

Range	1938	1939	1940	1941	1942
Mesabi	1,288,915,900	1,268,414,950	1,257,304,301	1,228,640,029	1,198,122,968

MINING BY STATES

Alabama.—Production of crude iron ore in Alabama in 1942 was 35 percent greater than in 1941. Mining activity in this State trended away from small operations; this is indicated by statistics which show that despite the increase in output there were only 47 active mines in 1942, compared with 76 in 1941. The small operators were unable to obtain much necessary equipment and labor. In addition, some of the operators entered the armed forces, and others went to work in war plants. Hematite represented 56 percent of the total crude-ore production in Alabama in 1942, and about 82 percent of the hematite produced was shipped direct to furnaces, 14 percent was sintered, and 4 percent was concentrated. In 1942, 55 percent of the total crude-ore production came from underground mines, most of which are in Jefferson County. The most important producing mines in this county were the Muscoda, Wenonah, and Ishkooda, which comprise the Red Mountain group, operated by the Tennessee Coal, Iron & Railroad Co. Other important underground mines in Jefferson County were the Spaulding and Raimund mines of the Republic Steel Corporation, the Woodward No. 3 mine operated by the Woodward Iron Co., and the Ruffner and Sloss Nos. 1 and 2 mines of the Sloss-Sheffield Steel & Iron Co. The usable hematite produced in Alabama in 1942 averaged (natural) 35.03 percent iron, 0.16 percent manganese, 0.32 percent phosphorus, 15.21 percent silica, and 14.97 percent lime.

Crude brown-ore (limonite) production in Alabama in 1942 amounted to 6,930,768 tons. This ore is mined by open-cut methods from a number of widely scattered deposits. All of this ore is concentrated before being consumed in blast furnaces. Log washers are commonly used for this purpose. Brown-ore concentrates produced in 1942 totaled 1,367,246 short tons, an increase of 12 percent over 1941. In 1942 the principal brown-ore mines were the Russellville Nos. 5,

Digitized by Google

11, and 12, operated by the Sloss-Sheffield Steel & Iron Co., the Giles mine of the Central Iron Ore Co., and the Martaban and Greeley mines of the Tennessee Coal, Iron & Railroad Co. Other important producers were the La Grange, Ironaton, Parish, Doc Ray, Waco, and Reno mines. Most of the brown-ore production came from Franklin, Tuscaloosa, Blount, Colbert, Butler, Talladega, and Cherokee Counties. Usable brown-ore production in 1942 averaged 46.0 percent iron, 0.63 percent manganese, 0.53 percent phosphorus, and 10.4 percent silica.

Arizona.—A small quantity of hematite was produced in Yuma County during the year. An open-cut mine is operated by E. E. Carlisle and produces ore for acid electric furnaces at Alhambra, Calif.

California.—The demands of the shipbuilding industry on the West coast caused 1942 usable iron-ore production in California to increase 78 percent over 1941. The Vulcan mine, an open-cut in San Bernardino County operated by the Kaiser Steel Co., made initial shipments of hematite to Fontana in December. Hematite from the Cave Canyon mine, the largest producer in the State, was shipped for consumption in cement manufacture. Magnetite from the Heroult mine in Shasta County was used largely for making concrete ballast blocks for shipping vessels. Shipments of usable ore in 1942 averaged 56.3 percent iron.

Georgia.—Virtually all of the output from Georgia is brown ore produced from open pits. Production of crude ore in 1942 totaled 1,506,265 tons, resulting in 334,342 tons of usable ore. The concentrating ratio of crude ore to usable ore was about 4.5:1. The outstanding producers in 1942 were the Porter, Woodward, Clemmons Hill, and Blanchard Reed mines and properties operated by the Mitchell & Hodge Co. and the Chulafinee Ore Co. Most of the ore came from Polk and Bartow Counties and relatively small amounts from Cherokee, Floyd, and Walker Counties. Shipments of usable ore from Georgia during the year averaged 47.3 percent iron and 0.59 percent manganese.

Michigan.—Output in Michigan comes from three ranges—Marquette, Menominee, and Gogebic. During the year the output from the Marquette range increased slightly, and the Menominee range showed a substantial gain, but production from the Gogebic range decreased slightly from 1941. Production in Michigan during 1942 totaled 17,499,060 short tons of usable iron ore, an increase of 6 percent over 1941. Underground mines supplied 94 percent of the total output in 1942. The iron content of ore produced in Michigan during the year averaged 51.68 percent, the same as in 1941.

The Negaunee and Maas mines, situated on the Marquette range and operated by the Cleveland-Cliffs Iron Co., were the leading producers in 1942, with 1,238,497 and 988,287 short tons, respectively. The Penn Group, Cliffs Shaft, Athens, Geneva-West Davis and Hiawatha Nos. 1 and 2 were also important producers. All of these underground mines produced hematite. The Plymouth mine on the Gogebic range was the largest open-pit producer in Michigan during the year.

Considerable expansion of the Michigan iron-ore industry was accomplished during 1942. The Sherwood mine of the Inland Steel Co., near Iron River, Mich., on the Menominee range, came into production in 1942. The Wauseca mine of the M. A. Hanna Co.,

Digitized by Google

also on the Menominee range, became an active producer in 1942, as did the Princeton mine of the Cleveland-Cliffs Iron Co. The Mather mine, at Ishpeming, Mich., owned jointly by the Cleveland-Cliffs Iron Co. and the Bethlehem Steel Co., was developed by the Negaunee Mine Co., although no output was reported in 1942.

A report of the iron-ore mines of Michigan for 1942, published by the Geological Survey Division of the Michigan Department of Conservation,[7] shows that the average number of men employed was 8,242 (7,553 in 1941), the average number of days worked 273 (248 in 1941), the average daily wage $7.60 (same as 1941), the average yearly earnings $2,073.53 ($1,885.79 in 1941), and the average tons of ore mined per man per day 6.75 (7.15 in 1941).

The data in the following table on average per-ton costs of mining ore at underground mines and at siliceous open pits have been abstracted from statistics published in much greater detail by the Geological Survey Division of Michigan.

Average costs, per short ton, of mining iron ore at underground mines and at siliceous open pits in Michigan in 1942

Item	Underground				Siliceous open pits
	Gogebic	Marquette	Menominee	Total	
Cost of mining:					
Labor	$1.0227	$1.1325	$0.9675	$1.0503	$0.2254
Supplies	.4950	.4875	.5192	.4999	.2154
Deferred costs	.2183	.0518	.1151	.1175	.0487
Taxes	.1954	.1470	.0899	.1409	.0417
General overhead	.1687	.1820	.1413	.1653	.0908
Transportation	1.6387	1.3601	1.4502	1.4773	1.3639
Marketing	.0000	.0860	.0696	.0742	.0714
Total ore cost	3.7988	3.4472	3.3528	3.5254	2.0573
Lake Erie value per ton	4.2196	4.1989	3.9412	4.1214	2.0771
Gross ore profit [1]	.4208	.7517	.5914	.5960	.0198
Other costs:					
Royalty	.3113	.2023	.2166	.2369	.0755
Interest on borrowed money	.0092	.0293	.0033	.0132	.0056
Federal income and excess profits	.1071	.1975	.0843	.1356	.0246

[1] This figure does not represent true profit, as much ore is sold below the Lake Erie price.

Minnesota.—A record total of 96,693,590 tons of crude iron ore was produced in Minnesota in 1942, an increase of about 18 percent over 1941; open-pit mines supplied about 94 percent of the total. Sixty-six percent of the crude ore shipped was for direct use in blast and steel furnaces, and the remainder was shipped to concentrating plants. Concentrates represented about 23 percent of usable ore shipped from mines in Minnesota, sinter accounted for less than 1 percent, and the remainder was direct shipping ore.

Three ranges (Cuyuna, Mesabi, and Vermilion) contribute to Minnesota's production. Production in 1942 from the Mesabi comprised about 96 percent of Minnesota's crude ore and 95 percent of usable ore output. In Minnesota 34 of the 101 active mines produced more than 700,000 tons of crude ore each during the year. The iron content (natural) of the usable ore produced in 1942 averaged 52.11 percent iron compared with 52.43 percent in 1941.

[7] Pardee, F. G., General Statistics Covering Costs and Production of Michigan Iron Mines: Michigan Dept. of Conservation, Geol. Survey Div., Lansing, 1943, 9 pp.

Digitized by Google

During the year, the Evergreen Mines Co. completed a concentrating plant at the Maroco mine, which will serve the Maroco and several other mines on the Cuyuna range.

Missouri.—Output of usable iron ore in 1942 totaled 59,180 tons, over three times the amount produced in 1941. The various properties of the Missouri-Cliffs Mining Co. supplied 83 percent of the State output. However, the Christy and Pioneer mines operated by the Missouri Mining Co. were important producers. Both hematite and brown ore were produced in Missouri; 93 percent came from open-pit mines. Usable ore shipped from mines in Missouri averaged 49.74 percent iron in 1942.

New Jersey.—Crude iron-ore production in 1942 totaled 1,494,853 tons, an increase of about 5 percent over 1941. The usable ore produced totaled 676,537 tons, a 7-percent decrease from the 1941 figure. To produce 1 ton of concentrates, 2.1 tons of crude ore were used in 1941 compared with 2.4 tons in 1942. This change in ratio may be caused by the variation of iron content in the ore; the proportion of ore to country rock mined; and the efficiency of the concentrator.

The Scrub Oaks mine, operated by the Alan Wood Steel Co., continued to be the outstanding producer in New Jersey. Other mines active in 1942 were the Mount Hope, Richard, and Washington. The magnetite ore is produced from underground mines in Morris and Warren Counties. The magnetite concentrates produced average (natural) 62.89 percent iron.

New Mexico.—Most of the iron ore produced in New Mexico in 1942 came from the El Paso iron claim in Grant County, operated by the St. Louis Smelting & Refining Co. Seven new mines in Lincoln and Socorro Counties supplied the remainder of the State output. The hematite and the magnetite that came from both underground mines and open pits were shipped direct to furnaces in Colorado. A total of 107,306 tons of ore was mined, averaging 54.85 percent iron. No production was reported in 1941.

New York.—The mining industry in the Adirondack district was greatly expanded during 1942. This expansion was not shown by production figures, because the activity was confined mostly to mine development and the construction of surface plants, although two new mines came into production on a small scale during the year. Late in the summer of 1942, the National Lead Co. made the initial shipments of magnetite and ilmenite concentrates from the MacIntyre mine [8] on Lake Sanford near Tahawus, Essex County. The Clifton mine near De Grasse, St. Lawrence County, was brought into production by the Clifton Ore Co. during the year. At the Clifton mine, most of the magnetite ore will be mined by underground methods, although open-pit methods of mining were used in 1942.

Surface structures, including magnetic separators and sintering plants, were under construction at the Benson mine in St. Lawrence County and the Fisher Hill mine near Mineville, Essex County. The magnetite deposit at the Benson mine will be exploited by the Jones & Laughlin Ore Co., using open-pit methods. At the Fisher Hill mine considerable underground development was done by the Republic Steel Corporation, although no production was reported during the year. A new inclined shaft, constructed at Mineville to serv-

[8] Matthews, Allan F., Minor Metals: Minerals Yearbook, 1941.

Digitized by Google

ice the Harmony-Old Bed-New Bed group should increase the output and efficiency of the mines by eliminating much rehandling of the crude ore. The Chateaugay mine at Lyon Mountain and the Mineville properties continue to be the outstanding iron-ore producers in the State. Shipments from New York State averaged (natural) 65.95 percent iron, 0.07 percent manganese, and 0.09 percent phosphorus.

Pennsylvania.—In 1942 the Cornwall mine, operated by the Bethlehem Steel Co., continued to supply virtually all of the ore produced in Pennsylvania. The magnetite ore body at Cornwall is mined by both underground and open-pit methods. The crude ore is hauled about 6 miles by rail to Lebanon, where all of the ore is concentrated and part of the concentrates sintered. In previous years the crude ore shipped from Cornwall was included with usable ore statistics. However, in 1942 a break-down is made between crude ore and usable ore, the concentrates and sinter shipped from Lebanon being included, for the first time; in usable ore statistics. It is believed that this new method of handling Cornwall figures will make the statistics more comparable with those of other magnetite mines, although the figures for this mine in 1942 will not be comparable with those for previous years.

The Hazard and Little Gap mines operated by the Prince Manufacturing Co. produced a small quantity of carbonate ore during the year.

Tennessee.—The treatment of copper-iron ores by the Tennessee Copper Co. at Ducktown results in the production of a considerable amount of pyrite ash. This residue is sintered and shipped for consumption in blast and open-hearth furnaces. The tonnage of this by-product material produced is included in usable ore statistics in 1942. Shipments of sinter during the year averaged 67.2 percent iron, 0.15 percent manganese, 0.007 percent phosphorus, and 2.2 percent silica.

Texas.—The Linden mine in Cass County was the only producer in the State in 1942; the brown ore shipped after concentrating averaged 52.5 percent iron.

Utah.—In 1942 the Iron Mountain mine operated by the Columbia Steel Co. continued to supply most of the iron ore output from Utah. The ore, principally semialtered magnetite, was mined by open-cut methods. Most of the ore was shipped to the blast furnace at Provo and contained (natural) 53.49 percent iron. The Great Western mine operated by Helene Beatty was the only other producer in the State.

Virginia.—The American Pigment Corporation mine in Pulaski County supplied virtually all of the output in 1942. The brown ore is mined from an open-cut and is consumed by the paint industry.

Washington.—Most of the ore produced in Washington during the year was from the Neutral mine in Okanogan County. This magnetite ore was used for ballast in war vessels. Some hematite was produced from the Napoleon mine in Stevens County and the Keystone mine in Pend Oreille County.

Wisconsin.—Production of crude hematite from underground mines in 1942 increased 5 percent over 1941. Ore from the Montreal Mining Co., averaged (natural) 52.48 percent iron, 1.26 percent manganese, 0.51 percent phosphorus, and 6.63 percent silica. The Cary mine, operated by the Odanah Iron Co., produced ore containing

Digitized by Google

(natural) 53.13 percent iron, 0.82 percent manganese, 0.05 percent phosphorus, and 6.07 percent silica. During the year a small quantity of ore was shipped from the Matilda-mine stock pile.

Wyoming.—The Sunrise mine in Platte County supplied all of the Wyoming output in 1942. Production came from both open-pit and underground operations by the Colorado Fuel & Iron Corporation. Shipments of hematite averaged (natural) 49.89 percent iron, 0.09 percent manganese, 0.06 percent phosphorus, and 12.95 percent silica.

EMPLOYMENT AT IRON MINES

Although complete information on employment at iron-ore mines in 1942 is not yet available, incomplete figures indicate that about 31,000 men worked 64,000,000 man-hours to produce 117,469,164 short tons of usable ore from domestic mines—an average of about 1.8 tons per man-hour and an all-time record. The man-hours worked in 1942 increased 6 percent over 1941, whereas the output of usable ore from domestic mines increased 13 percent; consequently, the output per man-hour increased 7 percent. The gain in output per man-hour was due mainly to open-pit mines, which represented 68 percent of the increase in production in 1942 over 1941.

WORLD PRODUCTION

The following table shows the production of iron ore by countries from 1938 to 1942, insofar as statistics are available. Although complete returns are not available, it is probable that world production established a new record in 1942 because of the large increase in United States production.

World production of iron ore, 1938–42, by countries, in metric tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	1938	1939	1940	1941	1942

SPONGE IRON

Considerable publicity was given to sponge iron during 1942 in view of an impending shortage of iron and steel scrap. Sponge iron of a usable grade for steel making can be produced by several techniques, including rotary and stationary kilns and multiple-hearth roasters. The economics of the operation depends on the scrap situation. When scrap is flowing to steel furnaces at a desired rate, sponge iron, if in powdered form, with more than a few percent of silica, and if special means of preventing entrance of sulfur during its production have not been used, would not be an economical melting stock in basic steel furnaces. However, during an emergency, the supply of scrap might not be adequate for maximum steel production and, with costs of secondary importance, there is little doubt that sponge iron could be used as a substitute for scrap. Early in our present steel-expansion program it seemed that such a shortage of scrap would develop; consequently, much publicity and speculation were given to the possibility of producing sponge in large quantities. Extensive use of sponge iron in steel furnaces would decrease steel-making capacity somewhat but would offset to some extent losses that might result from scrap shortages.

Except for metal powders, virtually no commercial sponge iron was produced in 1942. However, considerable progress was made in the development and construction of plants during the year. In October the War Production Board approved construction of a $450,000 sponge-iron plant at Youngstown, Ohio, as an experimental project to test the use of the material in electric furnaces. Likewise, funds totaling $600,000 were made available to the Bureau of Mines for construction and operation of sponge-iron pilot plants. Results of this work have not yet been made public.

PIG IRON

PRODUCTION AND SHIPMENTS

Domestic production of pig iron, exclusive of ferro-alloys, increased 7 percent in 1942 over 1941 and established a new record. The output in 1942 comprised 58,973,389 short tons using coke and 104,204 using charcoal as fuel. Pennsylvania was the largest producer of pig iron in 1942, with 31 percent of the total; Ohio ranked second, with 22 percent. Of the pig iron manufactured in 1942, it is calculated that 513,699 tons valued at $11,326,032 were made from 900,924 tons of foreign ores, including ore from Africa, Australia, Brazil, Canada, Chile, Cuba, India, Newfoundland, Spain, and Sweden, indicating an average yield of 57.02 percent from imported ore. Domestic ore (103,154,498 tons) and cinder, scale, and purchased scrap (7,741,210 tons) totaling 110,895,708 tons were reported as used in the manufacture of 58,563,894 tons of pig iron, indicating an average pig-iron yield of 52.81 percent from domestic materials. In addition, 1,564,912 tons of home scrap and 4,177,674 tons of flue dust were consumed in making pig iron in 1942.

[1] Included under "Undistributed."
[2] Includes statistics for States entered as "(1)."

Shipments of pig iron, exclusive of ferro-alloys, increased 7 percent in quantity and 10 percent in value in 1942 over 1941. The values given represent the approximate amounts received for the iron f. o. b. furnaces and do not include freight costs, selling commissions, and other items figured in some of the market prices for pig iron published by trade journals.

Pig iron shipped from blast furnaces in the United States, 1941–42, by grades

Grade	1941			1942		
	Short tons	Value		Short tons	Value	
		Total	Average		Total	Average
Charcoal	144,076	$3,618,686	$25.12	104,813	$2,860,086	$27.29
Foundry	3,125,413	61,309,626	19.62	2,656,089	53,221,988	20.04

VALUE AT BLAST FURNACES

The average value of all grades of pig iron given in the accompanying table is based upon reports of producers to the Bureau of Mines. The figures represent the approximate values f. o. b. blast furnaces and do not include the values of ferro-alloys. The general average value for all grades of pig iron at the furnaces was $20.77 a short ton in 1942, $0.64 more than in 1941.

Average value per short ton of pig iron at blast furnaces in the United States, 1938–42, by States

State	1938	1939	1940	1941	1942
Alabama	$13.10	$14.42	$14.30	$17.25	$17.30
Illinois	18.15	18.02	18.05	20.79	21.40

CONSUMPTION

Consumption of pig iron rose 5 percent in 1942 over 1941. Pig iron, a product of the blast furnace, is a semiraw material and, except for the small quantity used in direct castings, moves to other-type furnaces for further refining or mixture with other required ingredients. In general, it goes to steel-making or iron-making furnaces. By far the larger part is taken to steel-making furnaces (open-hearth, bessemer, and electric) for refining and processing into steel. In 1942, 88 percent of the pig iron was consumed in steel making. Direct castings took 4 percent of the 1942 total, and the remaining 8 percent was consumed in iron-making furnaces, of which the cupola is the most important. The consumption of pig iron, by types of furnace, for 1939 to 1942 is shown in the following table. The quantities of pig iron used in these furnaces are supplemented by the addition of ferrous scrap. The proportion of pig iron to scrap used in steel furnaces increased in 1942 over 1941.

Consumption of pig iron in the United States, 1939–42, by type of furnace

Type of furnace or equipment	1939		1940		1941		1942	
	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total
Open-hearth	26,826,172	76.2	36,297,250	78.6	42,481,404	75.6	45,538,846	77.1
Bessemer	3,603,199	10.2	3,828,978	8.3	5,993,264	10.7	6,131,222	10.4
Electric	30,542	.1	46,506	.1	72,758	.1	92,878	.2
Cupola [1]	3,349,198	9.5	4,106,119	8.9	5,388,747	9.6	[2] 4,490,532	7.6
Air Brackelsberg	329,317	.9	374,187	.8	604,835	1.1	555,436	.9

Puddling	27,959	.1	28,293	.1	54,183	.1	49,835	.1
Direct castings [1]	1,066,220	3.0	1,504,311	3.2	1,590,074	2.8	2,183,913	3.7
	35,232,699	100.0	46,185,828	100.0	56,185,472	100.0	[2] 59,042,883	100.0

[1] Some pig iron used in making direct castings included in cupola.
[2] Includes 19 tons used in making ferro-alloys.
[3] Less than 0.05 percent.

The consumption of pig iron in this country is widespread, and plants using pig iron are situated in all 48 States, the District of Columbia, and Alaska. As expected from the uses of pig iron, consumption is concentrated largely in the iron- and steel-making centers of the North Central, Middle Atlantic, and Southeastern States. These areas in 1942 used about 98 percent of the pig iron, Pennsylvania (the leading consumer) taking about 32 percent of the total and Ohio (the second-largest consumer) 20 percent.

[1] Pig iron is produced in Chile, New Zealand, and the Philippine Islands in addition to countries listed, but production figures are not available.
[2] Year ended June 30.
[3] Estimate included in total.
[4] Data not available.
[5] Estimated production.
[6] Approximate production as published by The Iron Age, vol. 147, No. 1, January 2, 1941, p. 61.
[7] Approximate production as published by Steel, vol. 196, No. 1, January 1940, p. 269.
[8] Included in the German figure in 1940.
[9] Beginning with March 1935, production of the Saar is included with that of Germany.
[10] January to October, inclusive.
[11] January to July, inclusive.
[12] Croatia only.

FERRO-ALLOYS

PRODUCTION AND SHIPMENTS

The production of ferro-alloys in 1942 totaled 1,889,409 short tons, compared with 1,636,073 tons in 1941—an increase of 15 percent. In 1942, ferro-alloys were made at 18 blast-furnace plants, 20 electric-furnace plants, and 3 aluminothermic plants. In addition, 3 plants made ferrophosphorus, and 2 plants made ferrosilicon as a byproduct. Of the 1942 total, 1,076,328 tons were made in blast furnaces, 778,112 tons in electric furnaces, and 33,427 tons by the aluminothermic process, and 1,542 tons of alloys were produced as byproducts. Shipments of all classes of ferro-alloys in 1942 increased 8 percent in quantity and 26 percent in value over 1941.

[3] Silicomanganese, manganese briquets, ferrochromium, chrome-manganese, ferrocolumbium, and zirconium-ferrosilicon.

Ferromanganese.—The output of ferromanganese in 1942 came from 11 blast-furnace plants and 3 electric-furnace plants compared with 10 blast-furnace plants and 3 electric plants in 1941. Of the manganese ore used in 1942, 98.6 percent was foreign ore. The ferromanganese produced in 1942 averaged 79.01 percent manganese. During 1942, steel producers used 12.4 pounds of metallic manganese as ferroalloys per ton of steel produced. Of this quantity, 11.2 pounds was in the form of ferromanganese. A total of 665,299 tons of ferromanganese was consumed in 1942—all by the iron and steel industry.

Ferromanganese produced in the United States and metalliferous materials consumed in its manufacture, 1938–42

Year	Ferromanganese produced			Materials consumed (short tons)				Manganese ore used per ton of ferromanganese made (short tons)
	Short tons	Manganese contained		Manganese ore (35 percent or more Mn, natural)		Iron and manganiferous iron ores	Cinder, scale, and purchased scrap	
		Percent	Short tons	Foreign	Domestic			
1938	272,153	78.65	214,036	466,746	25,254	10,860	9,477	1.808

[1] Tonnage entered under "Undistributed" comprises ore from India and U. S. S. R.; separation as to source not reported by consumer.
[2] Source of ore not reported by consumer.

Spiegeleisen.—The spiegeleisen produced in 1942 came from four blast-furnace plants, averaged 19 percent manganese, and had an average value of $31.86 per short ton at furnaces. All spiegeleisen in 1942 was manufactured from domestic materials and was made by the Carnegie-Illinois Steel Corporation, Pittsburgh, Pa. and the New Jersey Zinc Co., New York, N. Y.

Ferrosilicon.—Of the total of 712,710 short tons of ferrosilicon produced in 1942, 258,943 tons were produced in blast furnaces, 452,732 tons in electric furnaces, and 1,035 tons as a byproduct in the manufacture of artificial abrasives in electric furnaces. The silicon content of the production in 1942 ranged from 9 to 95 percent and averaged 30 percent. Blast-furnace production averaged about 10 percent silicon.

Ferrophosphorus.—The ferrophosphorus produced in 1942 averaged 24 percent phosphorus, and shipments were valued at $66.21 per short ton f. o. b. furnaces. All was made from domestic materials.

Ferrotungsten.—Production of ferrotungsten in 1942 totaled 14,216,680 pounds (7,108 tons), averaging 79 percent tungsten. The average value at furnaces was $1.899 per pound of contained tungsten and $3,014 per short ton of alloy. All ferrotungsten was made in electric furnaces.

Ferrochromium.—The industrial consumers of ferrochromium reported using 162,904 tons of ferrochromium during 1942.

Ferromolybdenum.—The bulk of the ferromolybdenum produced in 1942 was made by the aluminothermic process. All was produced from domestic ores and averaged 62 percent Mo.

Molybdic oxide, calcium molybdate, and molybdenum compounds.—As these products are used as alloying agents in the production of iron and steel, they are included with ferro-alloys. These compounds averaged 80 percent Mo in 1942. They are considerably less expensive than ferromolybdenum and consequently are used to a greater extent.

Digitized by Google

Ferrovanadium.—The ferrovanadium produced in 1942 averaged 38 percent V, and the value averaged $2.75 per pound of metal contained, at furnaces. This alloy is produced by electric and aluminothermic processes, using both foreign and domestic ores.

Silicomanganese.—The silicomanganese produced in 1942 averaged 67 percent manganese and was produced in electric furnaces.

Manganese briquets.—During 1942, manganese briquets averaged 56 percent Mn. Manganese briquets are used chiefly in the foundry industry.

Ferrotitanium.—During 1942, the ferrotitanium produced averaged 12 percent Ti. The bulk was made in electric furnaces, but some was produced by the aluminothermic process. Both foreign and domestic ores were consumed in the manufacture of ferrotitanium in 1942. Ferrotitanium is used chiefly as a deoxidizer and scavenger in steel making and is also valuable as an alloying agent in certain steels to prevent intergranular corrosion.

Ferroboron.—One hundred and ninety short tons of ferroboron containing 8 percent B were produced in 1942. Boron finds its main use in special steels as a hardening agent.

Ferrocolumbium.—Columbium additions have a valuable use in preventing intergranular corrosion. The production in 1942 averaged 57 percent Cb.

Zirconium-ferrosilicon.—The zirconium-ferrosilicon produced in 1942 averaged 14 percent Zr. Zirconium is a powerful deoxidizer and scavenger and reduces age hardening, thereby improving deep drawing properties of sheet steel.

FOREIGN TRADE

Imports and exports of the rarer metals are not recorded separately but are grouped as shown in the accompanying tables. Ferromanganese and spiegeleisen comprised most of the imports in both 1941 and 1942.

Ferro-alloys and ferro-alloy metals imported for consumption in the United States, 1941–42, by varieties

STEEL

GENERAL FEATURES

Steel production continued at a high rate throughout 1942, furnaces operating at an average of 97 percent of capacity for the year. Capacity for producing steel increased 1,723,000 short tons to reach a new record total of 90,293,000 tons. The data concerning steel operations used by the Bureau of Mines are furnished by the American Iron and Steel Institute. Not included in the statistics is the output from steel foundries that do not produce steel ingots. During 1942 the Bureau of Mines obtained some information to determine the magnitude of this tonnage. There are, in all, about 275 plants producing steel ingots and castings in the United States. In addition to the output of steel shown in the following table, 756,884 tons of basic open hearth and 228,630 tons of basic electric steel were produced for castings. Not known for 1942 is the quantity of bessemer steel, acid open-hearth steel, and acid electric steel produced by independent foundries that produce only castings. This quantity is relatively very small.

Bessemer-steel ingots and castings manufactured in the United States, 1938–42, by States, in short tons

[Includes only that portion of steel for castings produced in foundries operated by companies manufacturing steel ingots]

State	1938	1939	1940	1941	1942
Ohio	1,202,916	1,439,629	1,459,807	2,265,987	2,250,717
Pennsylvania	389,827	1,109,081	1,366,017	1,966,779	1,997,547
Other States	513,597	810,206	882,749	1,345,305	1,305,160
	2,106,340	3,358,916	3,708,573	5,578,071	5,553,424

Steel electrically manufactured in the United States, 1938–42, in short tons

[Includes only that portion of steel for castings produced in foundries operated by companies manufacturing steel ingots]

Year	Ingots	Castings	Total	Year	Ingots	Castings	Total
1938	524,843	40,784	565,627	1941	2,758,611	110,645	2,869,256
1939	951,522	77,545	1,029,067	1942	3,843,757	130,783	3,974,540
1940	1,608,032	91,974	1,700,006				

The steel output for 1942 includes 11,526,374 short tons of alloy-steel ingots and castings, which represent 13 percent of the total. This figure includes steels in which the minimum of the range specified in any of the elements named exceeds the following percentages: Nickel, 0.40 percent; chromium, 0.30 percent; copper, 0.50 percent; manganese, 1.65 percent; silicon, 0.50 percent; molybdenum, 0.10 percent; vanadium, tungsten, cobalt, titanium, and zirconium, any percentage. The output of alloy steels in 1942 increased 40 percent and that of total steel 4 percent over 1941. Of the total alloy-steel output in 1942, 65 percent came from basic open hearths, 5 percent from acid open hearths, 30 percent from electric furnaces, 522 tons from crucible furnaces, and none from bessemer converters.

Production of alloy-steel ingots and castings, 1938–42, by processes, in short tons

[Includes only that portion of steel for castings produced in foundries operated by companies manufacturing steel ingots]

Process	1938	1939	1940	1941	1942
Open hearth, basic	1,179,031	2,302,273	3,421,961	[1] 5,306,415	7,524,209
Open hearth, acid	102,089	156,581	252,965	433,240	608,867
Bessemer	13	3,486	3,990	3,890	----------
Crucible	5	231	255	933	522
Electric	372,372	749,384	1,286,716	2,461,651	3,392,776
	1,653,510	3,211,955	4,965,887	[1] 8,206,129	11,526,374

[1] Revised figures.

From the accompanying tables it will be seen that most of the steel made in electric furnaces (85 percent in 1942) is alloy steel. Typically, steels with higher alloy content are made in electric furnaces and steels with lower alloy content by the open-hearth process.

FOREIGN TRADE

Imports and exports of iron and steel products are given in detail in the following tables:

Iron and steel imported for consumption in the United States, 1941–42, by commodities

Commodity	1941		1942 [1]	
	Short tons	Value	Short tons	Value
Semimanufactures:				
Steel bars:				
Concrete reinforcement	6	$321	2	$442
Solid or hollow, n. e. s.	603	67,060	437	67,489
Hollow and hollow drill steel	250	34,897	1	253
Bar iron	17	1,671	1	324
Wire rods, nail rods, and flat rods up to 6 inches in width	119	36,699	57	14,165
Boiler and other plate iron and steel, n. e. s.	73	15,977	226	24,579
Steel ingots, blooms, and slabs	3,939	593,454	6,882	184,260
Billets, solid or hollow	181	15,227	281	34,609
Die blocks or blanks; shafting, etc.	17	7,623	54	13,264
Sheet iron and steel, n. e. s.	53	10,679	28	7,234
Tin plate, terneplate, and tagger's tin	122	31,330	117	27,945
Manufactures:				
Structural iron and steel	357	50,927	141	9,406
Rails for railways	7,672	200,796	14,431	426,607
Pipes and tubes:				
Cast-iron pipe and fittings	1	166	2	729
Other pipes and tubes	1,224	140,545	628	85,743
Wire:				
Barbed	[2]	21	[2]	5
Round wire, n. e. s.	39	9,426	89	10,187
Telegraph, telephone, etc., except copper, covered with cotton, jute, etc.	27	12,005	44	19,065
Flat and steel strips not thicker than ¼-inch and not over 16 inches wide	2,605	1,540,627	290	185,890
Rope and strand	105	21,823	36	9,331
Galvanized fencing wire and wire fencing	1	70	[2]	[2]
Hoop, band, or scroll iron or steel			1	232
Nails	31	9,262	229	11,081
Castings and forgings, n. e. s.	383	79,311	450	182,794

[1] January to November, inclusive; December figures not available at time of publication.

GENERAL PERSPECTIVE

The unprecedented demand for manganese by the steel industry resulted in a record consumption of manganese ore during 1942. Domestic production (shipments from domestic mines) in 1942, stimulated by higher prices, more than doubled the 1941 output and totaled 190,748 short tons; in 1941 shipments amounted to 87,794 short tons. In addition, 268,764 short tons of ore containing 10 to 35 percent manganese and 1,500,613 short tons of ore containing 5 to 10 percent manganese were shipped during 1942.

Although imports declined 15 percent in 1942, total domestic stocks decreased less than 1 percent and at the end of 1942 were sufficient to last at least 18 months. Because of the favorable continuation of imports during the war and the large stocks, much of the domestic expansion program outlined by the Bureau of Mines before 1942 has been deferred in favor of more critical raw-material programs. However, at the close of 1942 low-grade ores were being stock-piled by the Government for concentrating purposes, and stocks of such ore totaled 298,973 short tons (dry). The bulk of the ore is near Las Vegas, Nev., and in the Butte-Philipsburg area of Montana. Using these ores, the Manganese Ore Co. will produce 100,000 tons of ore annually from the Las Vegas operation, and the Domestic Manganese Co. will produce about 24,000 tons of concentrate from its mill at Butte. These operations are described in detail in this chapter in the section on Domestic Production.

Since the outbreak of war in Europe in 1939, the Bureau of Mines normal program of manganese research has been greatly expedited. By authorization of the Congress, Bureau of Mines and Geological Survey engineers intensified their search for domestic deposits containing manganese and other strategic minerals. In the fall of 1940 a $2,000,000 appropriation was made available to the Bureau for constructing and operating pilot plants to beneficiate low-grade manganese ores, to produce metallic manganese from these ores, and to develop

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Digitized by Google

manganiferous deposits. Since 1939 the Bureau has engaged in 37 projects for manganese exploration, has completed 34 of them, and still is working on three. In some projects a number of ore deposits were examined. As a result of this exploration, the estimated reserves of usable manganese ore in the United States have been increased several million tons. The Bureau of Mines believes that application of available processing methods to known ores can make the United States self-sufficient in manganese should imports decline to a point requiring the development of high-cost domestic production.

The electrolytic process, invented and developed by Bureau engineers between 1935 and 1938, extracts high-grade metallic manganese from low-grade ores through leaching and electrolysis. The process, patented and assigned to the United States Government through the Secretary of the Interior, is being used in a commercial plant at Knoxville, Tenn., as well as in the Bureau of Mines pilot plant at Boulder City, Nev.

Several shipments of 99.9-percent manganese from the Boulder City pilot plant have been sent to branches of the Mint at Philadelphia and San Francisco. Bureau metallurgists determined that several alloys using manganese have the physical and chemical properties required as a substitute for the 5-cent coin heretofore made of 75-percent copper and 25-percent nickel. The new coin, containing 9 percent manganese, 35 percent silver, and 56 percent copper, closely approximates the old coin in hardness, appearance, durability, and electrical resistance and may be used in coin-operated machines. Some attempts have been made to substitute less pure manganese, but the results have been unsatisfactory. By eliminating all the nickel formerly used in 5-cent coins, the adoption of the new alloy is releasing approximately 450 tons of this scarce metal and 250 to 350 tons of copper annually for the manufacture of war materials and essential civilian goods.

Salient statistics of the manganese industry in the United States, 1925–29 (average) and 1938–42, in short tons

	1925–29 (average)	1938	1939	1940	1941	1942
Manganese ore:

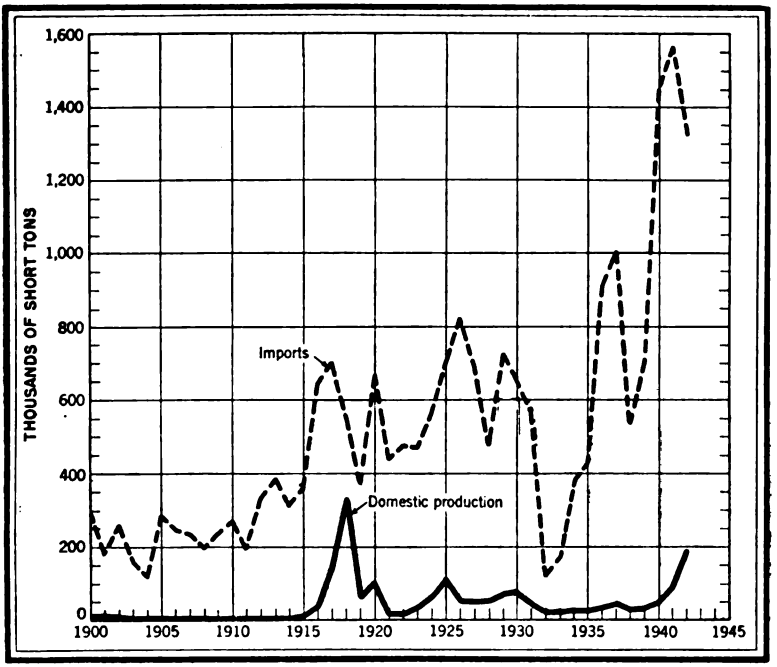

FIGURE 1.—Imports and domestic production (mine shipments) of manganese ore, 1900–1942. Statistics on imports shown in the graph represent general imports for 1900–1933, imports for consumption adjusted for changes in bonded warehouse stocks for 1934–39, and general imports for 1940–42.

Government purchases.—Government purchases of manganese ore proceeded at a high rate in 1942. The Metals Reserve Co. continued to purchase and stock-pile contract manganese ore during 1942, and on December 28, 1942, stock piles in 13 States (chiefly Maryland and Pennsylvania) contained 741,295 short tons of foreign ores and 147,558 short tons of domestic ores. The company also stock-piled noncontract manganese ore at 15 small-purchase depots, and on January 1, 1943, these piles contained 4,875 short tons of domestic ore. Purchases of low-grade ores for future milling increased greatly in 1942 and at the end of the year amounted to 298,973 short tons; most of the low-grade ore was held at Las Vegas, Nev., and at Butte, Mont.

DOMESTIC PRODUCTION [1]

The following table shows the various types of manganiferous materials shipped by domestic producers from 1938 to 1942.

Manganiferous raw materials shipped by producers in the United States, 1938–42, in short tons

Year	Metallurgical ore				Battery ore	Miscellaneous manganese ore
	Manganese ore (35 percent or more Mn)	Ferruginous manganese ore (10 to 35 percent Mn)	Manganiferous iron ore (5 to 10 percent Mn)	Manganiferous zinc residuum		
1938	19,027	37,655	308,269	43,768	5,554	3,778
1939	20,810	268,289	526,067	144,747	8,699	3,315
1940	30,416	358,406	914,526	172,990	10,383	4,137
1941	73,852	512,162	918,725	282,049	11,399	2,543
1942	177,966	265,663	1,500,613	292,051	15,410	473

Shipments of the various grades of manganese ores during the last 5 years are given, by States, in the following tables. In addition, battery-grade ores were produced in California and Montana; miscellaneous ores came from Alabama, Georgia, Montana, and Virginia; and manganiferous zinc residuum was produced from New Jersey zinc ores.

Alabama.—Only one shipment of metallurgical-grade manganese ore was made from Alabama during 1942; it came from the Cobalt Hill mine in Cherokee County. In addition, a small quantity of miscellaneous-grade ore containing less than 35 percent manganese was shipped from Etowah County during the year, and some ferruginous ore came from Calhoun County.

A study of the concentration of manganese-bearing ores from Walnut Grove, Ala., has been made by Johnston, Fine, and Shelton.[3]

Arizona.—A total of 2,946 short tons of metallurgical ore was shipped from mines in Arizona during 1942. The largest producer was the Black Warrior mine in the Artillery Peak district. Shipments from this mine were made to the Metals Reserve Co. and totaled 543 short tons. Other shipments of considerable size came from Coconino and Gila Counties. Fourteen shippers supplied the State total in 1942.

Arkansas.—The effect of the price ceiling was hard-felt in Arkansas during 1942. Production of manganese ore dropped to 4,132 short tons from 5,015 short tons in 1941. The operators could not pay for assaying before shipping and could not ship without knowing what the impurity penalty would be. Consequently, shipments of ferruginous manganese ore increased greatly from 3,381 short tons in 1941 to 14,067 short tons in 1942. In addition, 8,014 short tons of ferruginous manganese ore were shipped from mines to Government stock piles for later concentration. The ferruginous manganese ore in the Batesville stock pile on January 1, 1943, totaled 12,672 short tons (dry) averaging 26.45 percent manganese.

A study of the beneficiation of wad ore from the Ayedalotte property at Batesville has been made by Shelton, Fine, and Fisher.[4]

California.—Twenty-eight shippers from 17 counties supplied the total of 10,112 short tons of metallurgical ore and 2,856 short tons of battery ore containing 35 percent or more (natural) manganese. Among the larger producing mines in 1942 were the Whedon mines in Imperial County, the Pine Ridge, Barker, and Jones (Black Wonder) mines in Santa Clara County, the Buckeye and Tiptop mines in Stanislaus County, and the Manganese Queen and J. M. McKnight Group in Trinity County. An extensive program by the Geological Survey and the Bureau of Mines was under way in 1942 to investigate and evaluate deposits of manganese-bearing ores in California. Results of these investigations have not yet been made available to the public. The Bureau of Mines [5] examined the Arlington Manganese Claims in Riverside County and recorded the findings in a war minerals report.

Colorado.—The Pershing mine in Saguache County supplied the manganese ore shipped from Colorado during 1942. In addition, some ferruginous manganese ore was shipped from Gunnison County.

Georgia.—Georgia was the sixth-largest manganese ore-producing State in 1942. Of the total of 4,917 short tons shipped during the year, 4,715 tons came from the Cartersville district. This district

has shipped 205,600 short tons since operations began in 1866. The rest of the manganese ore shipped from Georgia in 1942 came from Lincoln County.

A Bureau of Mines proposal to exhaust the Cartersville manganese reserves in about 2 years during the present emergency was rejected by the War Production Board because of equipment shortages.

Massachusetts.—Anson G. Betts shipped ferruginous manganese ore from the Taconic mine in Hampshire County.

Michigan.—Ferruginous manganese ore totaling 34,643 short tons and averaging 13.11 percent (natural) manganese was shipped from the Bengal mine in 1942.

Minnesota.—What is believed to be the first manganiferous ore from the Mesabi range was shipped during 1942; the Corsica mine yielded 33,880 short tons averaging 6.49 percent (natural) manganese, and the Alpena mine shipped 10,765 short tons averaging 6.31 percent (natural) manganese. The rest came from the Alstead-Hillcrest Group, Hopkins, Louise, Merritt, Mahnomen, and Sagamore mines in Crow Wing County.

Fine and others[6] and Anderson[7] have studied the beneficiation of these ores.

Missouri.—The output of manganese ore from Missouri came from the Rocky Creek mine in Shannon County.

Montana.—Sixty-eight percent of the total metallurgical manganese ore and 77 percent of the high-grade battery ore shipped from mines in 1942 came from Montana. By far the largest operation in the State was the Manganese Reduction Works of the Anaconda Copper Mining Co. at Butte. In 1942 the ore was supplied by the Emma, Travona, and Anselmo mines. Battery-grade ore was shipped by the Moorlight Mining Co. and American Machine & Metals, Inc., from the Philipsburg district.

A Bureau of Mines proposal to erect a 400-ton custom mill at Butte, to treat manganese ores produced by several mines in that area, was approved by the Facility Review Committee of the War Production Board in March 1943.

The mill is to be constructed by the Domestic Manganese Co., which applied for a $250,000 loan from the Reconstruction Finance Corporation to finance the project. The Bureau of Mines in its exploratory work had drilled more than 10,000 feet of test holes, had taken many samples, and had tested the contemplated milling method. Known reserves of the four active mines in the area total about 175,000 tons of ore containing about 23 percent manganese. When milled and nodulized, the ore averages 51 to 59 percent manganese.

Under the contemplated program, the ore delivered to the mill will be purchased by the Metals Reserve Co., which has been buying ore for stock-piling in the Butte-Philipsburg region. The Domestic Manganese Co. proposes to mill and nodulize the stock-piled ore with the current production of the mines. When in full operation, the mill will produce about 2,000 tons of high-grade nodules per month. It is estimated that the milling plant can be constructed in about 90 days

and that its rated capacity of 400 tons of crude ore a day will be ample to handle the output of mines now producing and to accommodate any new operations in the field.

Nevada.—Manganese ore and ferruginous manganese ore were shipped from the Black Diablo mine in Humboldt County in 1942. Relatively small shipments were made from the Black Rock mine in Lander County and the Last Hope mine in White Pine County.

The Manganese Ore Co., subsidiary of the M. A. Hanna Co. of Cleveland, is developing claims in the Las Vegas Wash, about 18 miles southeast of Las Vegas, Nev., which will be one of the largest domestic producers of high-grade manganese ore. Although the property is popularly described as the Three Kids mine and operations are actually in the same vicinity, there is no activity at the old Three Kids. About 100,000 tons of concentrates will be produced annually when full operations have begun, but it is believed that only about half that quantity will be shipped in 1943. As the analysis of the ore as mined is not consistent, a bedding system is necessary. About 250,000 tons of ore were mined in 1942, averaging 18.86 percent (natural) manganese.

New Mexico.—Shipments were made from Dona Ana, Grant, Luna, and Valencia Counties in 1942. The largest producing mine was the Luna in Luna County. The shipment statistics given for New Mexico in the tables do not include 6,508 tons (dry) of ore shipped to Deming for subsequent concentration.

Oklahoma.—A small quantity of ore averaging 42.4 percent manganese was shipped from the Lucky 13 mine in Coal County during 1942.

Oregon.—The output from Oregon in 1942 came from the McAdams property in Coos and Curry Counties and averaged 44 percent manganese.

Pennsylvania.—J. Harry Simon produced the manganese ore shipped from Pennsylvania in 1942 from Sherman Valley, Bedford County.

South Dakota.—The North Star Manganese Producers shipped manganese ore from the August Schedlin mine in Lawrence County during 1942.

Tennessee.—A considerable decrease in usable manganese ore shipments from Tennessee was apparent in 1942. Most of the ore came from the Embree mine in Unicoi County; however, shipments were also reported from Blount, Carter, Johnson, and Sevier Counties.

Texas.—Two small lots of ferruginous manganese ore were shipped from Texas in 1942 for metallurgical purposes.

A study of the beneficiation of manganese-bearing ores from the Mayfield property at Van Horn has been made by Zadra and others.[8]

Utah.—Four shippers in Emery, Grand, and Juab Counties supplied the Utah total of 970 short tons of metallurgical ore and 78 short tons of ferruginous manganese ore during 1942.

Virginia.—Virginia was second only to California in number of shippers in 1942. Nine concerns shipped metallurgical-grade ore, 11 shipped miscellaneous-grade, and 5 shipped ores of both grades; in addition, 5 concerns shipped ferruginous manganese ore during the year. Shipments of manganese ore were made from Augusta, Bath, Bland, Campbell, Craig, Roanoke, Smyth, and Washington Counties.

Washington.—The Sunshine Mining Co. (second-largest shipper in

[8] Zadra, J. B., Fine, M. M., Shelton, S. M., and Johnston, T. L., Manganese Investigations—Metallurgical Division. 13. Ore-Dressing Studies of Manganese Ores. Concentration of Manganese-Bearing Ore from the Mayfield Property, Van Horn, Tex.: Bureau of Mines Rept. of Investigations 3632, 1942, 18 pp.

Digitized by Google

the United States in 1942) shipped from the Crescent mine in Clallam County the State total of 10,660 short tons of metallurgical ore, averaging (dry) 52.12 percent manganese.

West Virginia.—The Appalachian Ores Co. shipped 2,240 short tons of metallurgical ore from the Sweet Springs mines in Monroe County.

IMPORTS OF MANGANESE ORE

General imports of manganese ore containing 35 percent or more manganese decreased 15 percent from 1941 and comprised 7,963 short tons of battery ore and 1,316,361 short tons of other grades, chiefly for metallurgical use. In addition, 7,146 short tons of ferruginous manganese ore containing 2,086 short tons of manganese were imported during the year; of this quantity 4,413 tons containing 1,280 tons of manganese came from the Arabia Peninsular States, 2,240 tons containing 640 tons of manganese from Anglo-Egyptian Sudan, 490 tons containing 166 tons of manganese from Mexico, and 3 tons containing less than one-half ton of manganese came from Cuba. The bulk of the battery ore in 1942 came from Gold Coast (7,840 short tons containing 4,164 short tons of manganese); however, 67 short tons containing 36 short tons of manganese came from Canada, and 56 short tons containing 22 short tons of manganese came from Mexico.

Imports of manganese ore for consumption, which include ore withdrawn from bonded warehouses irrespective of date of entry, comprised 3,682 tons of battery ore containing 2,216 tons of manganese and valued at $86,372 and 1,557,258 tons of other grades containing 764,183 tons of manganese and valued at $22,922,524; in addition, 7,146 tons of ferruginous manganese ore were imported.

The accompanying table shows the details of imports in 1941 and 1942 of ore of all grades except ferruginous manganese.

Manganese ore (35 percent or more Mn) imported into the United States, 1941–42, by countries

Country	General imports [1] (short tons)				Imports for consumption [2]					
					Short tons				Value	
	Gross weight		Mn content		Gross weight		Mn content

CONSUMPTION AND STOCKS OF MANGANIFEROUS RAW MATERIALS

The total consumption of manganese ore in 1942 increased 13 percent over 1941 and amounted to 1,481,672 short tons; of this total, 1,435,388 tons or 97 percent was of foreign origin. Industrial stocks of manganese ore on December 31 were 26 percent less in 1942 than in 1941.

The accompanying table shows actual consumption of manganese ore (containing 35 percent or more manganese, natural) and alloys during 1942 and stocks at the end of the year.

Manganese ore and manganese alloys consumed and in stock [1] in the United States in 1942, gross weight in short tons

The accompanying table shows ores available for consumption in the United States in 1942 but does not consider consumer or Government stocks at the beginning and end of the year.

Indicated consumption of manganiferous raw materials in the United States in 1942

	Ore containing 35 percent or more Mn		Ore and residuum containing 10 to 35 percent Mn		Ore containing 5 to 10 percent Mn	
	Short tons	Mn content (percent)	Short tons	Mn content (percent)	Short tons	Mn content (percent)
Domestic shipments	190,748	53.3	560,815	14.9	1,500,613	8.0
Imports for consumption	1,560,940	49.1	7,146	29.2	[1] 1,780	6.2
Total available for consumption	1,751,688	49.6	567,961	15.1	1,502,393	8.0

[1] Estimated.

METALLURGICAL INDUSTRY

The bulk of the manganese ore (95 percent in 1942) used in the United States is for the manufacture of manganese alloys, and virtually all alloys are consumed by the iron and steel industry. During 1942 steel producers consumed 12.4 pounds of metallic manganese per ton of steel produced; of this, 11.2 pounds was in the form of ferromanganese, 0.6 pound as spiegeleisen, and 0.6 pound as silicomanganese. Ferromanganese producers used an average of 1.952 short tons of manganese ore per ton of ferromanganese produced.

Ferromanganese.—The domestic output of ferromanganese in 1942, which increased 14 percent over 1941, was produced at the following plants:

Bethlehem Steel Co., Johnstown, Pa.
Colorado Fuel & Iron Corporation, Pueblo, Colo.
E. J. Lavino & Co., Reusens, Va., and Sheridan, Pa.
Sloss-Sheffield Steel & Iron Co., North Birmingham, Ala.
Tennessee Coal, Iron & Railroad Co., Holt, Ala.
Carnegie-Illinois Steel Corporation, Etna and Clairton, Pa., and Gary, Ind.
Electro-Metallurgical Co., Alloy, W. Va., and Niagara Falls, N. Y.
Tennessee Products Corporation, Rockdale and Rockwood, Tenn.

In addition to the foregoing plants, shipments were made by the Keokuk Electro-Metals Co., Keokuk, Iowa.

Most of the ferromanganese produced in this country is made from foreign ores, as shown in the accompanying table.

[1] Tonnage entered under "Undistributed" comprises ore from India and U. S. S. R.; separation as to source not reported by consumer.
[2] Source of ore not reported by consumer.

Shipments of ferromanganese in 1942 increased 6 percent over 1941. The record of shipments for the past 5 years is as follows:

Ferromanganese shipped from furnaces in the United States, 1938–42

Year	Short tons	Value	Year	Short tons	Value
1938	250,566	$19,144,884	1941	619,395	$69,378,004
1939	332,227	24,137,211	1942	659,219	82,726,298
1940	503,291	42,755,485			

Imports for consumption and exports increased 110 and 39 percent, respectively, over 1941. Ferromanganese imported in 1942 totaled 14,772 short tons, all containing not less than 4 percent carbon.

Ferromanganese imported into and exported from the United States, 1938–42

Year	Imports for consumption			Exports [1]	
	Gross weight (short tons)	Mn content (short tons)	Value	Gross weight (short tons)	Value
1938	29,409	23,652	$1,770,948	277	$18,799
1939	46,175	37,424	2,935,214	3,274	247,798
1940	11,613	9,601	1,321,369	14,600	1,366,087
1941	7,032	5,696	557,150	5,155	771,575

Imports of ferromanganese in 1941 and 1942, by countries, are shown in the following table.

Ferromanganese imported for consumption in the United States, 1941–42, by countries

Country	1941		1942	
	Mn content (short tons)	Value	Mn content (short tons)	Value
Canada	1,202	$136,029	5,022	$654,219
Norway	13	1,597		
United Kingdom [1]	4,481	419,524	6,595	620,530
	5,696	557,150	11,617	1,274,749

[1] United Kingdom of Great Britain and Northern Ireland.

The quoted price per short ton of ferromanganese was increased from $111.90 to $125.58 May 1, 1942, in compliance with Office of Price Administration Price Regulation 138. No further change was in prospect at the close of 1942.

Prices per short ton of ferromanganese in the United States, 1940–42, by months [1]

Month	1940	1941	1942	Month	1940	1941	1942
January	$94.04	$111.90	$111.90	July	$111.90	$111.90	$125.58
February	94.04	111.90	111.90	August	111.90	111.90	125.58
March	94.04	111.90	111.90	September	111.90	111.90	125.58
April	94.04	111.90	111.90	October	111.90	111.90	125.58

June	94.04	111.90	125.58	December	111.90	111.90	125.58

[1] Steel, vol. 112, January 4, 1943.

Spiegeleisen.—Domestic production of spiegeleisen in 1942 increased 5 percent over 1941 and 63 percent over 1940.

Spiegeleisen produced and shipped in the United States, 1938–42

Year	Produced (short tons)	Shipped from furnaces		Year	Produced (short tons)	Shipped from furnaces	
		Short tons	Value			Short tons	Value
1938	12,668	27,932	$728,830	1941	177,915	181,177	$5,793,481
1939	102,470	94,908	2,484,042	1942	186,026	186,163	5,931,728
1940	114,119	119,512	3,487,565				

Spiegeleisen was manufactured at the following plants during 1942:

Carnegie-Illinois Steel Corporation, Clairton and Duquesne, Pa., and South Chicago, Ill.
New Jersey Zinc Co., Palmerton, Pa.

All the spiegeleisen produced in the United States in 1942 was made from domestic raw materials. Imports of spiegeleisen for consumption decreased 58 percent from 1941; the total supply came from Canada.

Digitized by Google

Spiegeleisen imported for consumption in the United States, 1938–42

Year	Short tons	Value	Year	Short tons	Value
1938	19,318	$625,480	1941	4,741	$215,108
1939	42,856	1,329,814	1942	1,990	95,853
1940	17,455	638,732			

The prices of spiegeleisen (20 percent) at producers' furnaces as quoted by Steel were constant at $32.14 a short ton throughout 1942.

Manganiferous pig iron.—Precise data on consumption of manganiferous ores in the production of manganiferous pig iron are not available. However, 1,500,613 short tons of domestic ore containing 5 to 10 percent manganese and 557,498 short tons containing 2 to 5 percent manganese were shipped during 1942. A small quantity (1,780 short tons) of foreign manganiferous iron ore and 13,950 short tons of foreign ferruginous manganese ore were also consumed in the manufacture of pig iron.

Foreign ferruginous manganese ore and manganiferous iron ore consumed in the United States, 1940–42, in short tons

Source of ore	Ferruginous manganese ore			Manganiferous iron ore		
	1940	1941	1942	1940	1941	1942
Africa	206					
Asia: Palestine	40,397					
Australia				13,334	2,265	790
Brazil	836	8,313	9,173			
Cuba			4,777			
Sweden				586		990
	41,439	8,313	13,950	13,920	2,265	1,780

BATTERY INDUSTRY

Shipments of battery ore containing over 35 percent manganese amounted to 12,377 short tons in 1942, and shipments of ore containing less than 35 percent manganese for battery manufacture totaled 3,033 short tons. It is believed that 1942 was the first year in which ferruginous manganese ore was purchased for this purpose. During 1942 the battery industry consumed 12,256 short tons of domestic ore and 24,246 short tons of foreign ore compared with 11,642 and 26,342 short tons, respectively, in 1941.

Manganese ore for battery use should have a high content of available oxygen with minimum iron and be relatively free from such metals as arsenic, copper, nickel, or cobalt, which are electronegative to zinc.

MISCELLANEOUS INDUSTRIES

During the last 4 months of 1942, 4,060 short tons of manganese ore were consumed in the chemical industries. Virtually all the chemical ore used in this country is of foreign origin; of the total consumed in 1942, only 57 short tons were of domestic origin. Chemical-grade ore has a great many uses, but most of it is used for photography, fertilizers, and coloring agents in paints and ceramics.

Digitized by Google

PRICES

Prices of manganese ore (except battery ore) are upon a unit basis, the unit being 1 percent of a long ton (22.4 pounds) of contained manganese. Prices of battery-grade ore are quoted upon a per-ton basis, with a minimum requirement of manganese dioxide.

Ferromanganese.—Standard ferromanganese containing 75 to 85 percent manganese was placed under formal price regulations on May 1, 1942. A price of $135.00 per long ton ($120.50 per short ton) f. o. b. Atlantic Seaboard, except for two Southern producers for whom the price is established on an f. o. b. furnace basis, was made effective in this order. This price represented an increase of $15.00 per long ton over the price which had prevailed since October 1–15, 1941. Other than manganese, standard ferromanganese was defined as metal containing a maximum of 1.25 percent silicon, 0.50 percent phosphorus, 7.50 percent carbon, and 0.05 percent sulfur. The maximum prices by grades were established as follows:

Kind or grade:	*Maximum price per long ton*
Containing 78–82 percent manganese	$135.00.
Containing less than 78 percent manganese but not less than 75 percent.	$135.00 less $1.70 for each 1 percent of manganese below 78 percent.
Containing more than 82 percent manganese but not more than 85 percent.	$135.00 plus $1.70 for each 1 percent of manganese in excess of 82 percent.

Manganese ore.—Maximum Price Regulation 248 was released October 27, 1942 (effective November 9, 1942), fixing the price of all manganese ore except battery and chemical ore at the following long-ton unit rates:

85 cents f. o. b. railroad cars Mobile and New Orleans.
90 cents f. o. b. railroad cars Norfolk, Baltimore, Philadelphia, and New York.
96 cents f. o. b. railroad cars Fontana, Calif.; Pueblo, Colo.; and Provo, Utah.

These prices are for metallurgical ore of a base analysis of manganese 48 percent, iron 6 percent, silica plus alumina 11 percent, and phosphorus not over 0.18 percent upon a dry basis. Premiums and penalties due to variation of analysis are as follows:

Premiums

Manganese content above 48 percent: ½ cent for each 1 percent.
Iron content below 6 percent: ½ cent for each 1 percent.
Silica plus alumina content below 11 percent: Nothing.
Phosphorus below 0.18 percent: Nothing.

Penalties

Manganese content:
- Below 48 percent: 1 cent for each 1 percent down to and including 44 percent.
- Below 44 percent: 4 cents, plus 1½ cents for each 1 percent down to and including 40 percent.
- Below 40 percent: 10 cents, plus 2 cents for each 1 percent down to and including 35 percent.

Iron content:
- Above 6 percent: 1 cent for each 1 percent up to and including 8 percent.
- Above 8 percent: 2 cents, plus ¼ cent for each 1 percent.

Silica plus alumina content:
- Above 11 percent: 1 cent for each 1 percent up to and including 15 percent
- Above 15 percent: 4 cents plus ¼ cent for each 1 percent.

Phosphorus content:
- Above 0.18 percent: ⅛ cent for each 0.01 percent.

The above premiums and penalties are applied pro rata to variations of a fraction of 1 percent.

Digitized by Google

Amendment 1 to Price Regulation 248 was issued November 30, 1942 (effective December 1, 1942), exempting metallurgical manganese ore with a manganese content of 40 percent or less. Previously ore of 35 percent or less manganese content was exempt.

The average mine value reported for ore containing 35 percent or more manganese during 1942 was about 72 cents per long-ton unit. Quotations on imported ore in the following table are from Engineering and Mining Journal. A duty of one-half cent per pound of contained manganese is imposed on all imported manganese ore except that from Cuba and Philippine Islands, which enters duty free.

Domestic prices of imported metallurgical manganese ore in 1942, in cents per long-ton unit

[C. i. f. North Atlantic ports, cargo lots, exclusive of duty]

	Beginning of year	End of year		Beginning of year	End of year
Brazilian, 46–48 percent Mn	$0.630	$0.788	Cuban (not dutiable):		
Chilean, 47–48 percent Mn	.650	.788	50–52 percent Mn	$0.780	$0.915
South African, 50–52 percent Mn	(1)	.788	45–47 percent Mn	(1)	.900

[1] Not quoted.

According to Engineering and Mining Journal, prices for chemical ores per long ton in carlots at the end of 1942 were as follows: Domestic, containing 70 to 72 percent MnO_2, $45 to $50; Brazilian or Cuban, 80 percent, $55; Javan or Caucasian, 85 percent, $70 to $75.

WORLD PRODUCTION

Brazil.—The bulk of the manganese ore from Brazil comes from the Morro da Mina mine in the Lafayette district in Minas Geraís and the Urucum mine in Matto Grosso. , During 1942, a total of 277,410 short tons was imported into the United States from Brazil, compared with 433,830 short tons in 1941. Brazil was our second-largest supplier in 1942.

Chile.—Production in Chile amounted to 32,692 short tons of 46- to 49-percent ore in 1942. Virtually none reached the United States during the year.

Cuba.—The Cuban American Managanese Corporation produced 198,286 long dry tons at the Isabelita mine in Oriente Province and shipped 159,686 long tons from Santiago and Antilla during the year. Stocks of ore at the mine and mill totaled 51,565 long tons at the close of the year.

French Morocco.—During the first 6 months of 1942, exports totaled 15,762 short tons.

Gold Coast.—Production in Gold Coast totaled 488,322 short tons in 1940 and 549,922 short tons in 1941. Stocks on hand October 31, 1942, at ports were 78,000 short tons and at mines 170,000 short tons.

India and Dependencies.—India was probably the world's largest producer of manganese ore in 1942—about 1,000,000 tons of ore is produced annually. During 1942 the United States received 493,197 short tons of ore from that country.

Turkey.—The production of manganese ore from Turkey comes from the Afyon and Eskisehir regions. During 1941 the output totaled

Digitized by Google

1,499 short tons and during the first 6 months of 1942, 569 short tons. The ore averaged 47 to 48 percent manganese.

Union of South Africa.—Data for only the first 11 months of 1941 and 1942 are available. During these respective periods, 460,161 and 404,462 short tons were produced.

U. S. S. R.—The Soviet Union continued to be a leading nation in manganese-ore production, but because of enemy occupation production dropped considerably in 1942—probably to less than 1,000,000 tons.

Manganese ore produced in principal countries of the world, 1938–42, in metric tons [1]

[1] In addition to countries listed, Belgium produces manganese ore, but data of output are not available. Czechoslovakia reports a production of manganese ore, but as it has been ascertained that the product so reported averages less than 30 percent Mn and therefore would be considered ferruginous manganese ore under the classification used in this report, the output has not been included in the table.

Production in 1942	634	World production	640

SUMMARY

The substantial increase in domestic chromite shipments to an all-time record of 112,876 short tons was an outstanding feature of the chromite industry in 1942—an achievement made possible through the opening of the Montana deposits, from which no commercial production had previously been realized. This large output represents the fruition of efforts by Government agencies to free the United States from complete dependence on foreign sources for its chromite supply. It must be remarked, however, that the quality of domestic chromite tends to offset in part the volume of shipments, as much of the product was unsuitable for metallurgical use. Concomitantly with the stimulation of domestic production, the Government has continued to develop its stock-piling program, whereby adequate supplies of foreign chromite are being procured to fulfill wartime requirements. The Government also undertook to correlate supply with requirements by placing chromium under complete allocation in 1942.

Salient statistics of chromite (ores and concentrates) in the United States, 1940–42

	1940	1941	1942
Shipments from domestic mines—			
By grades:			
45 percent Cr_2O_3 minimum ..... short tons	267	4,800	18,986
35 to 45 percent Cr_2O_3 ..... do	2,400	9,208	76,108
Less than 35 percent Cr_2O_3 ..... do	315	251	17,782
Total:			
Short tons	2,982	14,259	[1] 112,876
Value	$28,784	$274,062	$2,994,081
Imports for consumption:			
Short tons	736,612	1,115,292	980,487
Value	$8,754,770	$12,618,581	$14,184,159
Exports:			
Short tons	[1]	[2] 1,906	4,743
Value	[1]	[2] $72,409	$163,420

The U. S. S. R. is assumed to be the world's leading chromite producer. Next in order of importance are Southern Rhodesia, Union of South Africa, and Cuba. Thus the United Nations command the chief sources of supply. The Axis Nations control the output of continental Europe, which includes, as relatively important producers, Yugoslavia and Greece; they have also acquired the resources of the Philippine Islands, which in recent years had developed a significant production. With the little information at hand, it seems safe to estimate the Axis supply at not more than one-fourth the total world output. In the struggle to obtain larger supplies of chromite, Germany has made strenuous efforts to obtain the production of Turkey by trade negotiation. It is still doubtful whether this has actually been accomplished.

WAR REGULATIONS

Delivery of ferrochromium, other chromium alloys, and chromium metal was placed under Government control by the Office of Production Management in November 1941. The use of ferrochromium was limited to 2 tons per month without specific authorization in January 1942. The War Production Board extended allocation in February by requiring an application for all consumption of metallurgical chromium products.

The quantity of chromite that can be used in the manufacture of chromium chemicals has been restricted since November 1941, and the consumption of chromium chemicals has been controlled since March 1942.

A more detailed discussion of Government regulations appears in the chapter on Chromite in Minerals Yearbook, 1941.

MARKET AND PRICES

The Metals Reserve Co. has become the principal purchaser of domestic chromite since its buying program was announced in November 1941. Originally this Government agency undertook to contract for lots of 5,000 to 10,000 long tons of ore produced in continental United States, but in December 1941 the minimum size of contracts was lowered to 1,000 tons. In March 1942 the program was extended to include the purchase of trucklots of chromite produced in Oregon and northern California at nearby depots, with the object of encouraging production from small deposits in this region and providing an easily accessible market. Deliveries of ore to purchase depots in small lots did not constitute fulfillment of contracts. As defined in June 1942, small lots consisted of not less than 10 tons, the minimum quantity for which payment was to be made upon delivery. On September 10 the terminating date of the small-lot purchasing program was moved from April 1, 1943, to December 31, 1943.

The purchasing schedules have undergone several revisions with respect to type of material acceptable, grade and size of ore, and prices. Three grades, specifications for which are summarized in the accompanying table, were listed in 1942 schedules. The original minimum for Low-Grade A and B ore was 40 percent Cr_2O_3, but in the May 1942 revision of the schedule a minimum of 35 percent in these grades became acceptable.

The grades and prices (f. o. b. stock pile designated by buyer) established by Metals Reserve Co. follow:

Digitized by Google

	High-Grade	Low-Grade	
		A	B
Grade specifications:			
Cr_2O_3, percent minimum	45.00	40.00	40.00
Cr_2O_3, percent maximum	11.00	13.00	None
SiO_2, do	.20	.50	None
P, do	.50	1.00	None
S, minimum	2.5:1	2.0:1	None
Cr:Fe ratio	$40.50	$28.00	$24.00
Prices:			
Base, per long dry ton	.90	.90	.60
Premiums:	1.50	1.50	
Per unit Cr_2O_3 above minimum			
Per tenth increase in Cr:Fe from minimum to 3:1		1.40	1.20
Penalties (applicable to Low-Grade A and B only):			
Per unit Cr_2O_3 to 35 percent minimum			

Imported ores were given nominal quotations in E&MJ Metal and Mineral Markets during the first 10 months of 1942. Metallurgical-grade Indian and African ore (48 percent Cr_2O_3, Cr:Fe=2.8:1) was quoted at $39 per long ton, c. i. f. Atlantic ports, and Brazilian ore (48 percent, Cr:Fe=3:1) was priced at $41.

On November 3, 1942, the Office of Price Administration issued Maximum Price Regulation 258 for chromite ores. As explained in the memorandum accompanying the order, the ceilings are approximately at the levels prevailing during the first 6 months of 1942 for metallurgical and chemical ores and between the first half of 1942 and early November prices for refractory ores. The regulation, which became effective November 9, does not apply to sales of chrome ore to the Government or to sales where the contract of sale is made and title vests in the buyer while the ore is outside the continental United States. However, sales by Government agencies to private purchasers are included in the regulation. As a result, the Metals Reserve Co. may establish any price to stimulate domestic production and assure importation of adequate supplies of foreign ore. The maximum base prices are fixed f. o. b. railroad cars at various favorable basing points for industrial users (for example, New York, Philadelphia, Baltimore).

Maximum prices of chromite established by Office of Price Administration, effective November 9, 1942

Metallurgical-chemical ores:	
Analysis: Base—48 percent Cr_2O_3 and Cr:Fe=3.0:1; minimum—25 percent Cr_2O_3.	
Prices:	
Base, per long ton	[1] [2] $43.50
Premiums for—	
Increase in Cr_2O_3 above 48 percent, per long-ton unit	.90
Increase in Cr:Fe to 3.5:1, per tenth	1.25
Penalties for—	
Decrease in Cr_2O_3 to 25 percent, per long-ton unit	.90
Decrease in Cr:Fe to 2.0:1, per tenth	1.25
Refractory ores:	
Analysis: Minimum—25 percent Cr_2O_3.	
Base prices: [3]	
Lump ore (in bulk), per long ton	31.00
Ground ore, 24-mesh or coarser (in bulk), per short ton	36.50

[1] For Montana ores and concentrates only, base price is f. o. b. railroad cars at Columbus, Mont., with allowance to buyer for actual freight not in excess of $7.00 per long ton.
[2] Increase of $3.50 per long ton is allowed for sales and deliveries in lots of 1 carload or less.
[3] Quantity and packing differentials are provided; see Maximum Price Regulation 258 for details.

The Office of Price Administration also ordered that a maximum export premium of $6 per long ton might be charged on an export

Digitized by Google

sale of domestic chrome ore and concentrates containing 38 to 44 percent Cr_2O_3 as of November 9.

UNITED STATES

PRODUCTION IN 1942

The domestic production of chromite in terms of shipments from mines reached the unprecedented total of 112,876 short tons in 1942 or almost 8 times as much as in 1941. The previous record of 92,322 tons was made in 1918. In establishing the new record, Montana contributed over half the total. This is all the more remarkable as no shipments of chromite have ever been reported from Montana before. California produced 40 percent of the total, and the remainder was shipped from deposits in Oregon, Idaho, and Washington.

The average grade of chromite (ore and concentrates) shipped in 1942 was 39 percent Cr_2O_3. The highest average grade was produced in California (44 percent Cr_2O_3). Although Montana was the leading producer, the product was lowest in grade, averaging only 36 percent Cr_2O_3. Of the total shipments, 17 percent contained a minimum of 45 percent Cr_2O_3, 67 percent ranged in Cr_2O_3 content from 35 to 45 percent, and 16 percent contained less than 35 percent Cr_2O_3.

There were 150 shippers, and almost three-quarters of them operated in California. Two shippers in Montana and 11 in California supplied 90 percent of the total. Less than 30 percent of the shippers, all with production of over 100 tons, contributed 97 percent of the total.

Chromite (ore and concentrates) shipped from mines in the United States, 1900–1942

Period	Shipments from mines (short tons)					Total value
	California	Maryland and North Carolina	Oregon	Other States [1]	Total	
1900–1904	1,228				1,228	$15,852
1905–1909	1,119			423	1,542	23,345
1910–1914	1,442	95			1,537	18,680
1915	3,675				3,675	36,744
1916	49,009	100	3,471	100	52,680	726,243
1917	41,187	210	7,506	70	48,973	1,049,400
1918	70,725	533	20,669	395	92,322	3,955,567

[1] Idaho, Montana, Washington, and Wyoming.

California.—The new Grey Eagle mill of the Rustless Mining Corporation in Glenn County was the largest chromite producer in California in 1942. Production began in February and during the year totaled 11,153 tons of concentrates, averaging 46 percent Cr_2O_3 and 11 percent Fe. A roughly tabular mass about 800 feet long and 4 to 50 feet thick is now being mined. High-grade ore in stringers, streaks, and bands occurs in serpentinized dunite. Chromite is also disseminated through the host rock. The deposit is cut by faults,

Digitized by Google

which add difficulty to the mining operation. Allen [1] distinguishes at least six separate bodies in the Grey Eagle deposit. The crude ore ranges in grade from 5 to 25 percent Cr_2O_3. The mill heads averaged 12 percent Cr_2O_3 in 1942.

Flow sheets of the mill, which has a 200-ton capacity, and a description of both the mining and milling operation have been published.[2]

The Pilliken mine in Eldorado County was the leading producer of chromite in the United States from 1938 to 1941, inclusive. In 1942, the operation ranked fourth among domestic producers. The Pilliken deposit was mined during World War I. After a long period of virtual inactivity, United States Chrome Mines, Inc., erected a mill in 1937. The property was leased by the Rustless Mining Corporation from 1939 to 1942. The owners resumed operation in September 1942 and are rehabilitating the mill.

Total shipments from the Pilliken mine during the entire period of production have been about 30,000 tons. Over 8,000 tons consisted of shipping ore containing about 43 percent Cr_2O_3, and the remainder was composed of concentrates, which in 1942 averaged 42 percent Cr_2O_3 and 18 percent FeO.

High-grade lenses of irregular shape and distribution, containing 40 to 50 percent Cr_2O_3, were mined in the past, according to Wells,[3] who states that the future of the operation depends on blocking out large tonnages of milling ore, which carries about 10 percent Cr_2O_3.

In San Luis Obispo County the Castro mine was put into operation during 1942. Castro Chrome Associates, which operates the mine, erected a 125-ton mill at Goldtree Siding and began producing concentrates in May. The 1942 output amounted to 5,552 short tons averaging 41 percent Cr_2O_3 and with a Cr:Fe ratio of 2.5:1. The Bureau of Mines and Geological Survey have explored the Castro and nearby deposits.[4] The production from the district since 1870 has been about 50,000 tons of lump ore and about 7,000 tons of concentrates. Present reserves consist almost entirely of disseminated milling-grade ore. The crude ore mined in 1942 assayed about 20 percent Cr_2O_3.

The High Plateau mine in Del Norte County, operated by Eugene R. Brown, is the leading domestic producer of high-grade ore. According to an analysis published by Allen,[5] the ore contains 53.63 percent Cr_2O_3 and 13.75 percent FeO. In the same county, Tyson Chrome Mines, Ltd., shipped 1,521 short tons of ore averaging 42.3 percent Cr_2O_3 from the French Hill mine. Siskiyou County was the most active producing area in California, with over 20 shippers. The Cyclone Gap and Coggins mines, operated by J. K. Remsen, and the Come-Back mine (operators, Isgrig & Lilley) produced most from this county. Other properties in California with significant output were the McLaughlin & Applegarth mine in Tehama County, the Rivers mine of D. R. Moroney in Humboldt County, and the Victory

Digitized by Google

Chrome mine in Placer County. The last operation was described briefly by Huttl.[6] Space limitation precludes mention of the more than 100 additional producing properties in California.

Montana.—The development of the Stillwater deposits in Montana is the largest project yet undertaken to procure chromite from domestic sources. Explored by Government agencies since 1939, the equipment of a mine and construction of a mill were begun in 1941. The Anaconda Copper Mining Co., designated as operators for the Government, produced the first concentrates in the 400-ton Benbow mill in March 1942. In the 10 months of operation during 1942 the output of the Benbow mill exceeded the recorded annual production from any domestic chromite property.

The Stillwater Complex is a stratiform body of ultramafic igneous rocks, 30 miles long and 1 to 5 miles wide. It contains chromite deposits in lenses and discontinuous layers that form horizons paralleling the layering of the complex. No high-grade ore is known to occur in the complex, according to Peoples and Howland,[7] who have studied the deposits in detail. All the ore contains less than 40 percent Cr_2O_3.

The second-largest chromite operation in the United States in 1942 was also in Montana. The United States Vanadium Corporation mined ore from deposits in the vicinity of Red Lodge, Carbon County, beginning in October 1941. The chromite occurs in small serpentine intrusions on Hellroaring, Line Creek, and Silver Run Plateaus. Unlike the Stillwater deposits, those near Red Lodge are podlike. The grade of the ore ranges from about 40 to less than 25 percent Cr_2O_3, and the maximum Cr:Fe ratio is approximately 1.5:1. A mill was built at Red Lodge, and concentrates were first produced in March 1942. The milling operation was briefly described by Conwell.[8]

Oregon.—There were no large chromite producers in Oregon. Production increased from 840 short tons in 1941 to 2,683 tons in 1942. The Celebration mine in Grant County, operated by Hazeltine, Davis, and Byram, was the leading producer, with almost 500 short tons shipped. Next in order of shipments were the Sourdough and Hanenkrats mines of the Rustless Mining Corporation. The Sourdough mine in Curry County shipped 339 tons of chromite averaging 42.5 percent Cr_2O_3. The Hanenkrats mine in Grant County produced 248 tons of 40-percent ore. These three mines, with the Oregon Chrome and Black Beauty properties in Josephine County, supplied more than half of the output of the State.

Other States.—In Idaho, production of chromite was reported for the first time. The ore was produced from an occurrence south of Riggins in Idaho County by A. Brandenthaler, who also conducted an operation in Baker County, Oreg. Production in Washington was limited to the Fortune Creek mine in Kittitas County, from which a small shipment was made by the Skipper Chrome Mining Co. In Alaska, the Chrome Queen Mining Co. produced ore on Red Mountain, Kenai Peninsula, but no shipments were made before the end of the year.

EXPLORATION AND DEVELOPMENT

The large increase in domestic chromite production in 1941 and 1942 attests the amount of development in the last 2 years by private enterprise and Federal agencies. A few of the larger projects that have matured into active operations have been mentioned. In the near future important production is expected from the Mouat-Sampson deposit in the Stillwater district of Montana and from the Oregon beach sands. The Anaconda Copper Mining Co., agent for the Government, began mining on the Mouat-Sampson claims in the Stillwater Complex and prepared for concentrating the ores by building a mill to operate in 1943. This output will augment that from the Benbow mine and mill. In Oregon, beach sands in Coos County are the source of chromite that several companies plan to mine. The Krome Corporation has done experimental work since 1941 in this area. A concentrator is being erected at Bandon, Oreg., and a secondary chemical plant was planned at Marshfield. Two other companies—Humphreys Gold Corporation and Porter Bros. Corporation—were also actively engaged in developing production of chromite from the beach sands. In Alaska, preparations were made by the Alaska Juneau Mining Co. to mill chromite.

In 1942 the Bureau of Mines carried on an extensive development campaign throughout the Stillwater Complex in Montana. The Benbow and Mouat deposits were diamond-drilled, and further trenching and sampling of other areas were completed. As a result, several years' supply of chromite has been indicated ahead of present mining plans. Properties were also examined in California, Oregon, Georgia, and Alaska.

The Geological Survey continued its detailed studies of the Stillwater Complex, Mont.; John Day district, Oreg.; Claim Point and Red Mountain, Alaska; and Oregon beach sands. The Red Lodge (Mont.) and Knik Valley (Alaska) deposits were mapped, and a magnetic survey was made of some of the Red Lodge deposits. Many brief examinations were also made, mainly in the Pacific States and Alaska, and inventories of the deposits of several counties in California were prepared. Two reports [9] on work previously done in the Red Bluff Bay area, Alaska, and in Stanislaus County, Calif., were published during the year.

Mineral dressing of Oregon beach sands was given special attention by the Bureau of Mines. Methods were developed by which concentration of chromite in products containing more than 40 percent Cr_2O_3 can be made and other valuable minerals, such as zircon and garnet, recovered.[10] Tests have shown that the Oregon beach chromite concentrates with low Cr : Fe ratio can be improved to a metallurgical-grade product by the Bureau of Mines reducing-roast acid-leach process. Pilot-plant tests with this process on Montana concentrates were started at Boulder City, Nev.

USES AND CONSUMPTION

The market for chromite is created largely by the steel industry, which utilizes beneficial qualities imparted by the element chromium in certain alloy steels. Chromium is also employed in certain cast irons and nonferrous alloys. In addition to its value as a source of an alloying element, chromite is used widely for its refractory properties, especially in steel-making furnaces. Other applications of chromite are in chromium plating, pigments, dyes, and tanning.

Chromite is generally subjected to conversion (chemical or physical) processes to render it commercially usable. The most important of the initial conversion products is ferrochromium. This alloy is produced in various grades, which may be separated into two main groups upon the basis of carbon content. High-carbon ferrochromium, as sold in the United States, contains 4 to 6 percent C, whereas low-carbon grades range from 0.6 to 2 percent in maximum carbon. The chromium content of the alloy is roughly 60 to 70 percent, with higher percentages in the low-carbon grades.

As a refractory material, chromite is used in the form of bricks, cements, and plastics and also as crude lump or ground ore. In chemical applications the main raw materials made from chromite are sodium and potassium bichromate.

The consumption of chromite usually is measured at the point at which the ore is converted to one of the products mentioned above.

New supply and distribution of chromite (ore and concentrates) in the United States, 1940–42, in short tons

	1940	1941	1942
New supply:			
Domestic ore and concentrates	2,982	14,259	112,876
Imports for consumption	736,612	1,115,292	980,487
Total new supply	739,594	1,129,551	1,093,363
Distribution:			
Consumption	562,915	800,402	891,952
Exports	(1)	[2] 1,906	4,743
Total distribution	[3] 562,915	[3] 802,308	896,695

[1] Data not available.
[2] Figures cover July to December; not separately classified before July.
[3] Incomplete; see footnote 2.

The ore consumed can be classified into three grades, corresponding to the main categories of use. Chemical composition and physical properties distinguish these grades. The largest quantity consumed is metallurgical grade, followed in order by refractory and chemical grades. In 1942 metallurgical and refractory ores constituted 87 percent of the total chromite used, and chemical ore comprised only 13 percent. The Bureau of Mines has conducted monthly surveys of chromite consumption (and also production) since 1939, originally for Federal defense agencies and now for the War Production Board. This record is probably the most complete ever made of the chromite industry in the United States and has proved of vital importance in maintaining a continual record of supply of a strategic mineral under allocation. The total consumption, 1940–42, is given in the accompanying table. Stocks of all grades of chromite owned by industry and

Digitized by Google

the Government aggregated over 1,250,000 tons at the end of 1942. Industry stocks have declined progressively in the last three years, but Government stocks increased greatly. In 1942, the Government stocks exceeded those in private control.

IMPORTS AND EXPORTS [11]

Chromite imports in 1942 fell short of the record set in 1941 by 12 percent. Southern Rhodesia and Union of South Africa continued to be the main sources. Significant was the entry of U. S. S. R. into the list of countries from which chromite was obtained. The increase in imports from Turkey and Canada was also noteworthy.

No chromium compounds have been imported since 1939. A table showing imports of such compounds from 1937 to 1939 is given in Minerals Yearbook, Review of 1940, page 591. Ferrochromium imports in 1942 came from Canada only. They totaled, in terms of chromium contained, 6 short tons of grades containing 3 percent or more carbon and 436 tons of grades with less than 3 percent carbon. No chromium metal was imported in 1942. Imports of ferrochromium and chromium metal from 1937 to 1941 are shown in a table in the chapter on Chromite in Minerals Yearbook, 1941.

Exports of chromite were first recorded separately by the Department of Commerce for July 1941; in the latter half of 1941 they totaled 1,906 short tons. During 1942, 4,743 tons were exported, largely to Canada.

Crude chromite imported into the United States for consumption, 1938–42, by countries

Country	Gross weight (short tons)				1942		
					Short tons		Value
	1938	1939	1940	1941	Gross weight	Cr_2O_3 content

WORLD PRODUCTION

The progress of chromite production in foreign countries is difficult to appraise in wartime. The lack of information on production in the Axis-controlled countries is especially marked, but the same dearth of data is also noted for some of the United Nations. Thus, the level of production in U. S. S. R. is a matter of conjecture, although estimates suggest that that country is now and may well have been for several years the leading world producer. Reference to the accompanying world production table will show that no official statistics are available for any European or Asiatic country in 1941 and 1942. Not only is there an absence of statistics, but published comments on mining operations and developments are scarce. Next in order of output to U. S. S. R. are Southern Rhodesia, Union of South Africa, and Cuba. Turkey probably followed Cuba and slightly exceeded the United States in production during 1942. U. S. S. R. and Southern Rhodesia are the leaders in quantity of chromite produced and also in quantity of metallurgical ore. Union of South Africa is known as a source of chemical-grade chromite, whereas Cuba is principally a producer of refractory ore.

World production of crude chromite, 1938–42, by countries, in metric tons

Brazil.—The main deposits in Brazil are in the State of Baía The Cascabulhos, Pedrinhas, and Campinhos deposits near Campo Formoso and occurrences near Santa Luzia and Saúde contain the greater part of the reserves now known. Production has been small, probably slightly over 50,000 metric tons since 1918. Inadequate

Digitized by Google

rail facilities to the port of Baía have hampered development, as has the lack of water for milling in the Campo Formoso area.

A comprehensive discussion (with maps and analyses) of the chromite deposits in Baía was published in 1942 by Capper A. de Souza.[12] Reserves of high-grade ore at Cascabulhos and Pedrinhas are now estimated at 6,740 metric tons and probable ore is placed at 32,740 tons. For the entire Campo Formoso area, there are also estimated to be about 200,000 tons of low-grade ores to a depth of 25 meters.

Bulgaria and Yugoslavia.—The chromite deposits of the Skoplje region are included in the territory annexed by Bulgaria in the wartime dissolution of Yugoslavia. The addition of these resources will make Bulgaria the largest producer of chromite in Europe, assuming that the output is maintained at the former level. Pre-war Bulgaria was a very minor producer, mainly from deposits in the Krumovgrad district. The country's total output was 6,000 metric tons in 1940; Yugoslavia, on the other hand, produced about 60,000 tons of chromite annually.

The Skoplje region contributed 97 percent of the total output of Yugoslavia before the war.[13] Allatini Mines, Ltd., a British firm, was the leading producer, operating several properties, including the Orašje mine and a washing plant at Raduša with a daily capacity of 100 tons of ore. A new plant was planned, probably near Skoplje, to treat ores from both Yugoslavia and Greece. The shipping product included high-grade ore, concentrates, and grained ore (defined [14] as "a coarse granular product, eliminated in the earlier stages of concentration, which is used as a refractory"). Small deposits, grading 25 to 30 percent Cr_2O_3, in serpentinized peridotite bodies predominate. The iron content ranges from 12 to 16 percent, and in the concentrates SiO_2 ranges from 4 to 6 percent. A detailed discussion of the Skoplje deposits summarized from various studies is presented by Sampson.[15]

It is to be assumed that present operations are controlled by Germany, not only in the case of the Yugoslav deposits but also in those of Bulgaria proper. The supply from Yugoslavia is not as great as statistics of mine production would indicate, as most of the ore was concentrated. Approximately one-fourth of the crude ore is of shipping grade and part of this was treated with the washing ore.

Canada.—What has been called the greatest mineral discovery of the year in Canada was the finding of chromite in the Bird River area of southeastern Manitoba during the summer of 1942.[16] Samples of the chromite had been assayed in 1935, but no interest was evinced in the occurrence at that time. The chromite-bearing rock occurs near Bird Lake and to the north near Euclid and Maskwa Lakes. Three chromite zones, several thousand feet long and having a total width of 100 feet, are recognized in a peridotite mass. The main occurrences west of Bird Lake are apparently separated by faulting of an anticlinal structure. The tonnage of ore is said to be extremely large,

Digitized by Google

but the grade is low. The crude ore contains 16 to 20 percent Cr_2O_3, and preliminary tests indicate a possible concentrate of 36 to 40 percent with a Cr:Fe ratio of 1.25:1. At Euclid Lake the chromite bands are 26 feet wide, and the grade is reported to be higher than at Bird Lake.

The principal development work at Bird Lake has been done by God's Lake Gold Mines, Ltd., Gunnar Gold Mines, Ltd., and the Hudson Bay Mining & Smelting Co. Drilling has indicated ore to depths of 300 to 600 feet. Samples have been sent to the Department of Mines at Ottawa for testing. The studies are chiefly concerned with metallurgical problems posed by the low quality of the concentrates.

The Sterrett mine of Chromite, Ltd., at St. Cyr, Quebec, continued operating in 1942. The 50-ton mill began producing concentrates in December 1941. A description of the occurrence of chromite in the Eastern Townships, by Denis,[17] includes a discussion of the Sterrett mine. The Wartime Metals Corporation—a Canadian Government agency—had properties in this district examined, and one of them—the Bélanger deposit[18]—is being reopened. A new mill was scheduled to begin operation in April 1943 at a daily rate of 600 tons. Exploration was also undertaken in the Gaspé region along a serpentine belt described as more than a mile long and several hundred feet wide. The assays reported a content slightly exceeding 40 percent Cr_2O_3. Chromium Mining & Smelting Corporation, manufacturers of ferroalloys at Sault Ste. Marie, Ontario, was said to be interested in the Gaspé occurrences.

Cuba.—An extensive preliminary report on the chromite deposits of Cuba was published by the Geological Survey of the United States.[19] A few salient points are abstracted from this report. In 25 years from 1916 onward, 795,277 short tons of Cuban chromite were imported into the United States. About 85 percent of this amount consisted of refractory ore, and the remainder was metallurgical ore. The Cuban deposits are irregular masses of variable size occurring in serpentinized peridotite belts along most of the northern coast. Mining has been limited to the eastern half of the island. The chief sources of the Cuban ore have been the Camaguey district and eastern Oriente Province. The latter area includes the Mayari district, a source of metallurgical ore analyzing 55 to 58 percent Cr_2O_3 and with a Cr : Fe ratio of about 3.4 : 1. Refractory ore from the Camaguey district contains 30 to 32 percent Cr_2O_3, 28 to 32 percent Al_2O_3, and about 5 percent SiO_2. In most districts the grade of ore is fairly constant. The field work of the Geological Survey was expanded during 1942, especially in Oriente Province.

Greece.—The entire output of chromite in Greece is concentrated and shipped to the Krupp Works in Germany, according to a recent report. The operating properties are apparently the St. Athanasius mine at Xinia and the Apostolides mine at Tsagli in Thessaly, the Vrioni mine in Macedonia, and the Papostoriou mine near Kozani in Thessalonikē. The monthly rate of production from the mines was about 5,000 tons at the end of 1942.

New Caledonia.—Although New Caledonia has not been the leading chromite producer since 1920, its output continues to be outstanding in quality. In 1942 the average grade of New Caledonia ore and concentrates imported into the United States was 53 percent Cr_2O_3. The annual rate of production is now estimated at over 75,000 short tons. Chromite has been produced in New Caledonia for 65 years, and the output has totaled approximately 2,000,000 tons. The principal deposits are in the Tiébaghi Dome in the northern part of the island and have yielded more than 75 percent of the total output but currently are producing about one-half the annual total. The Tiébaghi mine is one of the largest in the world, having produced roughly 1,500,000 tons of ore averaging 55 to 57 percent Cr_2O_3. Other properties in the Tiébaghi Dome are the Fantoche, Alpha, and Chagrin mines.

Turkey.—More space has been devoted to the subject of the disposition of Turkey's chromite after expiration of the Anglo-Turkish agreement on January 8, 1943, than to any other aspect of the world chromite industry. The German-Turkish agreements concluded in October 1941 and reported in the American and British press at that time were known to involve Turkey's chromite. The provisions apparently called for exchange of German war materials with a value of £T18,000,000, to be delivered during 1942, for 90,000 to 100,000 tons of chromite in both 1943 and 1944. The agreement was looked upon with misgiving, as it was stated that "The matter from the Allied viewpoint has been of importance, not so much from the angle of assuring supplies to Britain and her Allies, but of depriving the Germans of strategic material."[20] Subsequent statements on the provisions of the agreement varied somewhat, so that a complete version as of the beginning of 1943 is quoted here:[21]

> Between January 15 and March 31, 1943, Turkey and Germany will exchange goods to the value of £T55,000,000, including 45,000 tons of chrome on the Turkish side, and war material of the value of £T18,000,000 on the German side. It now seems to be established that the Germans will obtain supplies of chrome in proportion to the amount of war material and other goods delivered by them to Turkey by the end of March 1943. According to the same agreement Germany may obtain from Turkey an additional 45,000 tons of chrome during the rest of 1943, and another 90,000 tons in 1944, against delivery of war material to Turkey, but these further deliveries become operative only if Germany has delivered by March 1943 the entire quantity of war material provided for in the first paragraph of the agreement.

Considerable skepticism was displayed as to Germany's ability to deliver goods acceptable to Turkey, and it was also suggested that Turkey was dissatisfied with goods so far received. There is nothing to indicate whether an actual exchange has taken place. It is noteworthy that Great Britain is reported to have resumed conversations with Turkey with a view to renewing their agreement. Also, Germany was reported in April 1943 to have negotiated further exchange of goods, but whether chromite was included is not known.

Production of chromite in Turkey has apparently decreased since 1938. One estimate from a German publication [22] gives 80,000 metric tons for 1941; at the same time it is suggested that an increase will result from the German agreement. It is stated that the chrome-

mining areas in western Turkey are being exploited more fully again after a period of years during which the eastern deposits were most important.[23] The Eti Bank, state mining bank of Turkey, was said to have received over £T1,000,000 to expand chrome mines.[24]

U. S. S. R.—In 1942 the United States imported 30,061 short tons of chromite averaging 52 percent Cr_2O_3 from U. S. S. R. The principal deposits are in the Urals. Official information on production since 1936 has been entirely lacking. An unofficial British estimate[25] placed 1940 production at 400,000 tons of 48-percent ore. In 1940 a statement was made to the effect that production of 600,000 tons a year was planned by 1942.[26] Reserves of chromite in the U. S. S. R. were estimated[27] to be 15,194,000 metric tons at the beginning of 1934. Of this total, 13,748,000 tons were in Saranovo, Sverdlovsk Province.

United Kingdom.—Refractory-grade chrome ore occurs on the island of Unst, Shetland Islands. It was mined during the last century and again in small quantities during and since World War I. In a recent report, Wilson[28] states that between 1922 and 1927 about 3,000 tons were produced; 323 tons were shipped in 1936, 710 tons in 1938, and 1,100 tons in the year ended July 31, 1940. The ore now worked contains about 26 percent Cr_2O_3. Typically the ore analyzes 25 to 45 percent Cr_2O_3, 10 to 20 percent SiO_2, and 5 to 12 percent Al_2O_3.

Chrome-magnesite bricks produced from Shetland chromite have proved satisfactory in trials in open hearth and arc furnaces. The product compares favorably with brick made from Greek chrome ore.[29]

Production	646		

SUMMARY

As a result of larger imports of nickel and the elimination of nonessential civilian and some military uses, conservation measures, and salvage of nickel-bearing scrap, the available supply was apparently adequate for vital war needs of the United States in 1942. So far as known, no shut-downs of essential war production due to lack of nickel supplies occurred during 1942. Nevertheless, so great was the demand that at no time during 1942 were domestic stocks of primary nickel more than a month's supply. An important conservation measure in the United States was the development of the National Emergency steels. These steels, some of which contain 0.2 to 0.7 percent nickel, were brought into being to spread the available alloys as widely as possible. No primary nickel is required for these steels. According to Butzner:[1]

NE steels, with their huge savings of nickel and vanadium, were first produced in May, but the first heavy production was in August, when they made up 30 percent of the alloy production. In August a new and still more economical series was announced. The monthly production has since reached as much as 50 percent and will of necessity go higher. The proportion will fluctuate quite considerably month to month, depending on fluctuating emphasis on gun steels, for example, which are still high-nickel.

Production of nickel in Canada in 1942 was about the same as in 1941, but in New Caledonia it declined slightly. The expansion program of the International Nickel Co. of Canada, Ltd. (announced in 1941), entailing an expenditure of $35,000,000, has progressed to a point where it now assures an increase in productive capacity of 50,000,000 pounds of nickel annually over the 1940 rate of production. The expansion program of Falconbridge Nickel Mines, Ltd., begun in 1941, was completed about the middle of 1942.

In 1942, as heretofore, the domestic output of primary nickel was insignificant. In addition to the nickel produced as a byproduct in the electrolytic refining of copper and as secondary nickel, a little was recovered as a byproduct of talc production in Vermont.

The St. Louis Smelting & Refining Co. did development work at its properties near Fredericktown, Madison County, Mo., where nickel and cobalt occur with lead, copper, and iron. The complexity of the ore presents a problem in metallurgy. However, the Bureau of Mines has studied the metallurgical problems involved, and the results of laboratory and pilot-plant tests at Rolla, Mo., indicate that fairly satisfactory recoveries can be made in cobalt-nickel and copper-lead concentrates by selective flotation. Exploratory drilling was done by the Freeport Sulphur Co. on a nickel deposit near Riddle, Douglas County, Oreg. Some prospecting was reported at the long-idle nickel property near Lancaster, Pa.[2]

Based upon the field work of the Bureau of Mines and upon data made available from other sources, a number of War Minerals Reports[3] on nickel deposits were prepared for the confidential use of Federal war agencies.

The Geological Survey published reports describing the nickel deposits of Yakobi Island, Alaska,[4] and near Gold Hill, Colo.[5]

The Dillon nickel prospect in Montana was described by Sinkler.[6]

PRODUCTION

Domestic production of nickel is small and comprises secondary metals recovered from scrap-nickel anodes, nickel silver, and copper-nickel alloys (including Monel metal), and primary metal recovered in copper refining and produced from ore and as a byproduct of talc production, as listed in the following table. Domestic primary nickel was recovered in 1942 as a byproduct in copper refining at Baltimore, Md., Laurel Hill, N. Y., Perth Amboy, N. J., and Tacoma, Wash. Concentrates containing 10 percent nickel and 0.78 percent cobalt were recovered as a byproduct of talc production in Vermont; however, none were shipped.

FOREIGN TRADE [7]

The nickel imported into the United States in 1942 comprised chiefly metallic nickel, matte, and oxide. As heretofore, Canada was the chief source of the imports; it supplied 61,003,121 pounds of matte, 161,151,775 pounds of metallic nickel, 23,837,605 pounds of oxide, and 1,990,000 pounds of residues. The matte from Canada, which contains approximately 55 percent nickel and 25 percent copper, is refined to Monel metal and other products at the plant of the International Nickel Co., Inc., Huntington, W. Va. New Caledonia supplied 19,472,399 pounds of matte; it contains about 78 percent nickel and is also refined at Huntington, where a new plant was completed in 1941 for refining matte from New Caledonia and elsewhere. About 7,200 short tons of nickel were produced at Huntington from New Caledonian matte in 1942. Cuba supplied 117,602 pounds of ore (presumably); the United Kingdom 117,304 pounds of oxide and 383,170 pounds of metallic nickel; and Mexico and Switzerland 40,007 and 178 pounds, respectively, of metallic nickel.

The nickel content of the unmanufactured nickel products imported into the United States is estimated at 228,550,000 pounds in 1942, as compared with 212,363,000 pounds in 1941. Imports of nickel in 1942 established a new peak.

Exports of nickel comprise largely products manufactured from imported raw materials. Exports of metallic nickel, Monel metal, alloys, and scrap increased 9 percent over 1941, whereas nickel-chrome electric resistance wire almost doubled. Exports of nickel silver, however, declined 91 percent. The United Kingdom (7,927,986 pounds), U. S. S. R. (3,076,692 pounds), and Canada (2,079,398 pounds) were the chief markets for nickel, Monel metal, alloys, and scrap in 1942.

Brazil.—The nickel deposits at São José do Tocantins, State of Goyaz, and at Livramento, State of Minas Gerais, have been described in considerable detail by Wright and Pardee.[8] A brief summary of the deposits will be found in Minerals Yearbook, 1941.

According to the American Smelting & Refining Co.: [9]

The company acquired a 50-percent interest, together with a term management contract, in a nickel property in the State of Goyaz, Brazil. This property was carefully examined by four of the company's senior engineers. Their reports indicate there is a very large tonnage of ore, containing a percent of nickel that should assure a profitable operation. The ore is refractory, but the company's research department succeeded in working out a process which will recover the nickel. The mine contains cobalt in commercial amounts, and extraction of this metal will probably begin in advance of the nickel operation. It is planned first to erect at Perth Amboy (N. J.) a small pilot plant, and with knowledge gained therefrom to design a commercial plant to be constructed at the property during 1944, although as regards completion much will depend on nonpredictable factors, such as ability to obtain the necessary material, equipment, and shipping facilities.

Canada.—Virtually all the Canadian output is derived from the copper-nickel ores of the Sudbury district, Ontario; and two companies—International Nickel Co. of Canada, Ltd., and Falconbridge Nickel Mines, Ltd.—are the principal producers. Production in Canada was 141,616 short tons in 1942, compared with 141,129 tons in 1941 and 122,779 tons in 1940.

The International Nickel Co. of Canada, Ltd.,[10] stated:

It is gratifying to report, as forecast a year ago, that the increase in production of nickel in all forms of 50,000,000 pounds over the 1940 output has been realized. Work on production expansion has progressed according to schedule and is largely completed. All of the company's works ran continuously throughout the year and, considering the shortage of labor and the difficulty in securing supplies, the operating results were satisfactory.

According to Falconbridge Nickel Mines, Ltd.: [11]

All treatment plants were operated at maximum capacity throughout the year, though with considerable difficulty at times due to the construction programs which were being carried out. On the whole the result achieved may be viewed with satisfaction, since a substantial increase both in tonnage treated and in production is again recorded. The program to expand capacity begun in 1941 was completed by the middle of the year. This project included additional crushing equipment at the shaft head; some increase in storage-bin capacity and handling equipment; grinding mills; flotation equipment and additions to thickening and filtering capacity in the mill; additional sintering capacity and changes in the smelting plant, together with the provision of added and improved change-house facilities both at mine and smelter.

The Alexo nickel property, which produced nickel during the First World War, is again to be a contributor, arrangements having been made for the sale of the ore.[12]

According to the Northern Miner: [13]

Nickel Offsets, Ltd., is proceeding with the deepening of the shaft at its property in Foy and Bowell Twps., Sudbury district. In previous work the shaft was sunk to 530 feet, with a large amount of development carried out at the 200, 350, and 500-foot levels. It is now proposed to go down to 1,250 feet and to cut stations at 150-foot intervals as sinking proceeds.

Digitized by Google

A deposit of high-grade nickel ore has been developed at the Moose mine, near Sudbury, by the Ontario Nickel Corporation; equipment has been partly installed for a daily output of 300 tons.[14]

Cuba.—According to the Freeport Sulphur Co., which, through its subsidiary, Nicaro Nickel Co., is constructing a plant in Cuba for the production of nickel: [15]

> A great deal of time and thought of this organization has gone into pushing the construction of this plant during the past year. It is difficult to say when production will start, because the commencement of operations is dependent upon the priorities which we may receive for the equipment necessary for the completion of the plant.

Finland.—A Swedish engineering firm is erecting automatic heating apparatus for the mining town of Kilosjoki, where the mines of Petsamo Nikkeli O/Y are situated.[16] The town will shelter the 3,000 workers and officials of the nickel-mining company.

With the assistance of German materials and engineers, the mine (Petsamo), which was considerably damaged in the first Russo-Finnish conflict, has been restored and production resumed.[17] Another nickel deposit has been discovered in central Finland at Nivala; preparations for production are in progress.

A plant now under construction by the Outukumpu O/Y at Pori, the first of its kind in the country, will eventually supply 400 tons of nickel a year.[18] Meanwhile, the company is producing copper-nickel ore at the rate of 18,000 tons a year, most of which is probably being sent to German refineries.

New Caledonia.—New Caledonia ranks second in world production of nickel. The Société Le Nickel owns a number of properties in various parts of the island, but the most important are those around Thio on the east coast and around Voh and Koné on the west coast. The smelter, comprising four furnaces, is at Noumea and produces a matte containing 77.5 to 78 percent nickel for export. About 90 percent of the ore smelted comes from the mines of the company, and 10 percent is purchased from small miners. For several years previous to the war, shipments of ore were made to Germany and Japan by the small miners.

Nickel ore treated in and matte exported from New Caledonia, 1938–42

Year	Ore treated		Matte exported (long tons)				
	Long tons	Percent nickel (average)	Australia	Belgium	France	United States	Total
1938	241,131	4.5	----------	4,194	3,710	----------	7,904
1939	248,020	4.0	----------	2,569	6,586	----------	9,155
1940	296,246	3.5	[1] 3,143	----------	[1] 4,724	----------	7,867
1941	292,309	3.5	[2] 394	----------	----------	7,756	8,150
1942	264,752	3.5	738	----------	----------	6,417	7,155

[1] Of these quantities, 1,019 tons destined to Australia and 883 tons destined to France were reexported to the United States in 1941.

COBALT

By H. W. Davis

SUMMARY OUTLINE

	Page		Page
Summary	651	Uses	653
Production	651	World production	653
Foreign trade	653		

SUMMARY

Despite prohibitions and limitations on the use of cobalt for many purposes, total consumption in the United States was about 12 percent greater in 1942 than in 1941. There was a marked increase in consumption of cobalt in stellite and stellite-type alloys, magnets and magnet steels, and carbide-type alloys; but this gain was partly offset by a decline in the amount used in ground-coat frit, pigments, and driers. Although domestic production of cobalt made considerable gain in 1942, most of the demand, as heretofore, was supplied by imports, mainly in the form of alloy from Belgian Congo and ore from Canada. The domestic ore, which averages about 1.4 percent cobalt, is processed to metal, oxide, and hydrate at Wilmington, Del. The alloy from Belgian Congo contains about 40 percent cobalt and is converted to metal and oxide at Niagara Falls, N. Y., and to oxide, sulfate, catalytic salts, or driers at Chicago, Ill., Cincinnati and Cleveland, Ohio, Elizabeth, N. J., New Brighton, Pa., and Richmond, Calif. The Canadian ore, which averages about 11 percent cobalt, is processed to cobalt oxide and other products at Cincinnati, and to cobalt-nickel oxide at Canonsburg, Pa., and Cleveland, Ohio. A new cobalt-nickel plant was being built at Cleveland, Ohio, to treat Burmese speiss, which contains about 7 percent cobalt, 30 percent nickel, 40 percent arsenic, and 10 percent copper. The products contemplated are cobalt oxide, nickel oxide, copper oxide or hydroxide, and calcium arsenate. It is expected that the plant will be ready for operation about May 15, 1943. In the plant, room is provided for the addition at a later date of smelting equipment for treating Canadian concentrates containing about 10 percent cobalt, 3 percent nickel, and 25 percent arsenic.

Domestic quotations for metal in 100-pound lots and for black oxide in 350-pound lots remained unchanged throughout 1942 at $1.50 and $1.84 a pound, respectively. These prices have been in effect since the latter part of October 1939.

PRODUCTION

Though comparatively small, production of cobalt ore in the United States increased considerably in 1942; the Bethlehem Steel Co., Beth-

Digitized by Google

lehem, Pa., was again the chief producer and shipper. The cobalt (averaging about 1.4 percent) is contained in the sulfides that accompany the magnetite mined at Cornwall, Pa. The Eastern Magnesia Talc Co., Inc., Burlington, Vt., recovered 50 short tons of concentrates, containing 0.78 percent cobalt and 10 percent nickel, as a byproduct of froth flotation of talc. The Sullivan Mining Co., Kellogg, Idaho, recovered 64 short tons of residue, containing 5.66 percent cobalt, at its electrolytic zinc plant. At the Columbia mine near Goodsprings, Nev., Otto F. Schwartz did some development work and shipped 1 short ton of concentrates averaging 6.96 percent cobalt.

The St. Louis Smelting & Refining Co. did development work at its properties near Fredericktown, Madison County, Mo. By December 1942, a new shaft had been sunk to 400 feet; two additional shafts are contemplated in 1943. At these properties cobalt and nickel occur with lead, copper, and iron, but the complexity of the ore presents a problem in metallurgy. The property was visited by a Bureau of Mines engineer in August 1942, and a report [1] was prepared showing the production possibilities of the deposits and indicating the metallurgical testing undertaken by the Bureau to determine a suitable treatment method. Results of the Bureau's laboratory and pilot-plant tests at Rolla, Mo., indicate that fairly satisfactory recoveries can be made in copper-lead and cobalt-nickel concentrates by selective flotation.

After examinations in 1941 and June 1942, the Bureau of Mines in August 1942 undertook an exploration and ore-testing project on a group of claims of the Uncle Sam Mining & Milling Co., Inc., in the Blackbird district in east-central Idaho. By the end of 1942, sampling of underground workings had established a moderate tonnage of positive ore averaging 2.06 percent copper and 0.29 percent cobalt, with additional values in gold and silver. This sampling also provided a basis for estimating a considerable tonnage of geologically inferred ore. Further surface and underground exploration, including sampling, drifting, and crosscutting, are planned for 1943. Ore testing of samples at the Salt Lake City Experiment Station of the Bureau has shown that good recovery of cobalt, copper, and gold can be made by bulk flotation in a concentrate that is of low grade with respect to cobalt. Fair recovery of cobalt in a separate cobalt concentrate of better grade was obtained by selective flotation and tabling. Results of the preliminary examinations and plans for Bureau exploration are discussed in a recent report.[2]

Small amounts of cobalt are associated with many manganese ores, but the cobalt is not extracted in the usual metallurgical and chemical processing of these ores. The Bureau of Mines determined early in its development of the electrolytic manganese process that most of the cobalt goes into solution together with the manganese in the leaching step and is precipitated with other impurities upon purification of the leach solution. In view of this potentially large source of cobalt and the difference of opinion as to whether leach solutions containing cobalt can be purified sufficiently for satisfactory electrodeposition of manganese, tests were made at the Boulder City (Nev.) electrolytic manganese pilot plant of the Bureau on the separation and electrodeposition

Digitized by Google

of manganese and cobalt from manganese electrolytes. These tests proved that appreciable concentrations of cobalt in manganese solutions can be eliminated sufficiently to allow satisfactory electrodeposition of manganese and that recovery of cobalt from the sludge residue of the manganese-electrolyte purification is feasible.

FOREIGN TRADE[3]

Imports.—Imports of cobalt into the United States in 1942 were 30 percent less than those in 1941, which, however, was a peak year. The chief source of imports in 1942 was Belgian Congo, which supplied 7,928,952 pounds in the form of an alloy containing 3,208,687 pounds of cobalt. Canada supplied 148,304 pounds of cobalt (metal) and 834,797 pounds of ore containing 91,597 pounds of cobalt, and the United Kingdom 200 pounds of salts and compounds of cobalt.

Cobalt ore, metal, oxide, and other compounds of cobalt imported for consumption in the United States, 1938–42

Year	Ore			Metal		Oxide		Sulfate		Other salts and compounds	
	Pounds		Value	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value
	Gross weight	Cobalt content

[1] Data not available.

Exports.—Exports of cobalt were 118,866 pounds valued at $162,039 in 1942. From July to December 1941 exports totaled 34,341 pounds valued at $37,670; exports of cobalt before July 1, 1941, are not separately recorded.

USES

The largest single use of cobalt is in stellite or stellite-type alloys, and such alloys absorbed about 39 percent of the total cobalt consumed in 1942. Other important uses of cobalt are in magnets and magnet steels, high-speed steels and other cutting-tool materials, valve steel, welding rod, and carbide-type alloys; these outlets comprised about 44 percent of the cobalt consumed in 1942. Smaller quantities of cobalt are employed in the ceramic industry, in the preparation of driers, in electroplating, as a catalyst, and for a variety of other uses. Of the total cobalt consumed in 1942, 10 percent was used in driers, 5 percent in ceramics, and 2 percent for electroplating, catalyst, and other applications.

WORLD PRODUCTION

As cobalt production data for many countries are lacking, it is impossible to prepare an accurate statement of world output. Never-

[3] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Digitized by Google

theless, world production for 1942 is estimated at 5,000 to 5,500 metric tons. With the occupation of French Morocco, the United Nations control about 85 percent of the world output. The following table shows world production by countries, 1937–42, insofar as statistics are available.

World production (partly estimated) of cobalt, 1937–42, by countries, in metric tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	Cobalt-bearing material	Cobalt content					
		1937	1938	1939	1940	1941	1942
Australia	Cobalt ore	(2)	(2)	(2)	(2)	(2)	5
Belgian Congo	Cobalt alloy	1,500	1,532	(2)	(2)	(2)	2,200
Bolivia (exports)	Cobalt ore	(2)			2	2	28
Burma	Cobaltiferous nickel speiss	[4] 298	[4] 238	[4] 229	218	73	(2)
Canada	Cobalt ores, oxide, and metal	230	208	332	360	119	39
Morocco, French	Cobalt ore	581	720	719	700	700	400
Northern Rhodesia	Cobalt alloy	[4] 578	[4] 1,073	[4] 1,598	(2)	(2)	(2)
United States	Cobalt ore				(5)	(5)	(5)

[1] In addition to the countries listed, Brazil, Chile, China, Finland, Germany, Italy, Japan, and Mexico produce cobalt, but production data are not available. The world total for 1942 is estimated at 5,000 to 5,500 tons.
[2] Data not available.
[3] Less than 1 ton.
[4] Year ended June 30 of year stated.
[5] Bureau of Mines not at liberty to publish figures.

Belgian Congo.—Belgian Congo is the world's chief source of cobalt. Cobalt is mined as such and as a high-grade copper-cobalt ore. Cobalt also occurs with sulfide and carbonate copper ores, from both of which partial recovery is made by concentration. Production data have not been published since 1938, when 1,532 metric tons were produced. Since then, however, it has been reported that further reserves of rich cobalt minerals have been discovered, the Kabolela cobalt mine has been developed, a concentrator has been installed, and a fourth electric furnace added. As a consequence, production undoubtedly has increased considerably and may have reached 2,200 tons in 1942. Two additional electric furnaces were under construction in 1942 which, when in operation, should increase production to above 3,000 tons.

Brazil.—Cobalt is associated with nickel at Jacuba, São José do Tocantins, State of Goyaz. The American Smelting & Refining Co. (New York, N. Y.) recently acquired a 50-percent interest in the Companhia Niquel Tocantins and will construct a pilot plant at Perth Amboy, N. J., to refine nickel from ore from the properties in the State of Goyaz. Extraction of cobalt probably will be begun in advance of the nickel operation.

French Morocco.—French Morocco ranks third as a world producer of cobalt. With the occupation of this country by the United Nations, the Axis-controlled countries lost access to its cobalt supplies, which have been allocated to the United States by the Combined Raw Materials Board.

Northern Rhodesia.—Northern Rhodesia is the second-largest producer of cobalt in the world. Cobalt in association with copper is produced at the Nkana mine of the Rhokana Corporation, Ltd. The

Digitized by Google

copper ore contains 0.02 to 0.5 percent cobalt in the form of sulfide, and by special processes, involving differential flotation of certain of the ores and treatment of the converter slags, a rich cobalt-iron-copper alloy is produced.[4] The alloy contains about 40 percent cobalt and at present is exported to Canada for refining. Recent production figures are not available, but in a statement circulated with the annual report of the Rhokana Corporation, Ltd., for the year ended June 30, 1942, it was reported that the largest possible amount of cobalt had been produced and was still being produced, in spite of the many difficulties that had to be overcome. During the year ended June 30, 1939, alloy containing 1,598 metric tons of cobalt was produced.

SUMMARY

Molybdenum is produced in many parts of the world, but compared with the United States there is no producer of importance. The combined output of all other countries is less than 10 percent of the world total, and most of that comes from Western Hemisphere countries and Norway and French Morocco. Reliable estimates of output in European and Asiatic countries under the influence of the Axis are not available, but no established producer of any note, except Norway, would fall in that category.

In 1942 all earlier records for domestic production of molybdenum were exceeded. Output of molybdenum in ore and concentrates in the United States rose 42 percent to 57,077,000 pounds; the Climax Molybdenum Co. produced approximately 73 percent of the total, and all but about 3 percent of the remainder was byproduct recovery from three copper operations. Imports of molybdenum ordinarily are a negligible factor in the available supply; although still relatively very small, in 1942 they amounted to 755,950 pounds in ores and concentrates, the greater part of which came from Chile. Exports increased 52 percent in 1942 to 11,617,517 pounds.

Molybdenum has been used so extensively to replace less abundant steel-alloying metals that measures for its conservation have been adopted by placing it under complete allocation (WPB General Preference Orders M–110 and M–110–a) and by reducing the Mo content of alloy steels in the new NE (National Emergency) series.

Salient statistics of the molybdenum industry in the United States, 1940–42

	1940	1941	1942
Concentrates:			
Production.....short tons..	33,128	38,962	56,239

WAR REGULATIONS

All forms of molybdenum, including scrap, were placed under complete allocation by War Production Board General Preference Order M–110, dated March 18, 1942 (effective May 1). On August 8 this order was amended to permit the melting of molybdenum only after approval of melting schedules, as provided in Order M–21–a, and to extend the effective time of the order until revoked. The original provision exempting users of less than 50 pounds monthly from reporting their requirements was modified on November 6 by an amendment (M–110–a) permitting, under certain conditions, deliveries up to 500 pounds of contained molybdenum in any one month without allocation. Melters whose requirements are not large may use up to 500 pounds monthly without submitting melting schedules to the War Production Board. On January 9, 1943, secondary molybdenum chemicals were removed from the M–orders on molybdenum.

An order of the Board of Economic Warfare provided that, as of July 9, 1942, molybdenum ore and concentrates, products, alloys, and scrap could be exported under general license only to Canada and Newfoundland. An individual license is required for clearance of exports of these molybdenum-bearing materials to all other foreign countries.

MARKET

The quoted price for molybdenum ore refers to molybdenum in concentrates containing 90 percent MoS_2. The price has held at 45 cents per pound (equivalent to 75 cents per pound of molybdenum contained) f. o. b. mines for several years. In practice, the price is said to vary with the grade. The molybdenite concentrates are shipped largely to processing plants for conversion to molybdenum oxide, calcium molybdate, ferromolybdenum, etc. The prices of the principal molybdenum products are based on a pound of contained molybdenum, f. o. b. producer's plant. Molybdenum oxide and calcium molybdate are priced at 80 cents and ferromolybdenum at 95 cents.

UNITED STATES

PRODUCERS IN 1942

Only seven ore deposits were exploited actively during 1942 for their molybdenum content. One of them, the Climax deposit, is the world's largest molybdenum producer. All but two are operated mainly for their yield of other metals. Among the group that produces molybdenum as a byproduct is the Bingham copper deposit, second-largest producer of molybdenum in the United States. The chief ore of molybdenum is molybdenite (MoS_2); wulfenite ($PbMoO_4$), once mined from several deposits in southwestern United States, is now extracted at a single mine.

Domestic shipments of molybdenum in ore and concentrates in 1942, amounting to 66,437,000 pounds, were 74 percent greater than

Digitized by Google

in 1941 and represent about 23 percent of the total shipments since 1918.

Molybdenum in ore and concentrates shipped from mines in the United States, 1914–42 [1]

Year	Pounds	Value [2]	Year	Pounds	Value [2]
1914–18	1,601,643	$2,070,213	1939	32,415,000	$22,157,000
1919–23 [3]	355,493	370,371	1940	25,329,000	17,189,000
1924–28	8,498,343	6,160,304	1941	38,200,000	25,883,000
1929–33	18,954,917	11,406,000	1942	66,437,000	47,299,000
1934–38	94,077,000	64,244,000	1914–42	285,868,396	196,778,888

[1] For shipments by years, 1914–38, see chapter of this series for 1941.
[2] Largely estimated by Bureau of Mines.
[3] No shipments in 1920 and 1921.

Climax and Questa are the only molybdenum deposits now operated solely for their content of this metal. In 1942 Climax produced 73 percent of the total United States output of molybdenum. Questa is a very much smaller operation but has been a consistent producer for 20 years and thereby has contributed substantially to the domestic production of molybdenum during that period.

The Climax deposit in Colorado has been discussed extensively in literature, as have the various aspects of the mining and milling operation. In 1942, Vanderwilt [1] summarized the ore occurrence, and a review of Climax is presented in the discussion of domestic deposits in the chapter of Minerals Yearbook, 1941, on Molybdenum and Vanadium.

Molybdenum contained in concentrates produced from Climax deposit in Colorado, 1918–42 [1]

Year	Pounds	Year	Pounds
1918–37 [1]	80,060,256	1941	27,751,273
1938	28,242,085	1942	41,852,136
1939	21,796,116		
1940	22,782,608	1918–42	222,484,474

[1] For production by years, 1918–37, see chapter of this series for 1941. No production from 1920 to 1923, inclusive.

Molybdenite near Questa, Taos County, N. Mex., was first recognized during World War I. The deposit was developed by the R & S Molybdenum Mines Co., and about 100,000 pounds of molybdenum in concentrates were produced in 1919 and 1920. The Molybdenum Corporation of America acquired ownership in 1920 and built a mill and camp in 1923. Since that time the property has been in regular operation.

The mine is in Sulphur Gulch, 7 miles east of Questa; the mill is on Red River, three-quarters of a mile from the mine. The deposit covers an area about half a mile square, on the western flank of the Sangre de Cristo Range, at an elevation of 8,000 to 9,000 feet. Accord-

[1] Vanderwilt, John W., The Occurrence and Production of Molybdenum: Colorado Sch. Mines Quarterly, vol. 37, No. 4, October 1942, p. 38. Structure of the Climax Molybdenite Deposit (in Ore Deposits as Related to Structural Features): Princeton Univ. Press, 1942, pp. 136–137.

Digitized by Google

ing to Vanderwilt,[2] mineralization is in fissure veins near the contact of a small granite mass with a series of sedimentary and volcanic rocks. Numerous iron-stained fractures mark the mineralized area at the surface. The deposit is unique in the production of large quantities of molybdenite from veins and is likewise outstanding in the richness of the ore (about 5 percent MoS_2).

Mining and milling methods employed by the Molybdenum Corporation of America at Questa have been described by Carman.[3]

Production of molybdenum in concentrates at Questa is summarized in the accompanying table.

Molybdenum contained in concentrates produced from Questa deposit in New Mexico, 1919–42

Year	Pounds	Year	Pounds	Year	Pounds	Year	Pounds
1919	65,492	1925	332,293	1931	469,800	1937	499,182
1920	34,900	1926	334,412	1932	515,588	1938	438,672
1921		1927	285,833	1933	571,500	1939	477,327
1922		1928	450,264	1934	571,956	1940	484,120
1923	22,667	1929	475,925	1935	342,000	1941	466,856
1924	140,239	1930	639,852	1936	405,000	1942	376,285

Molybdenite is present in all the important disseminated-copper deposits in southwestern United States and Mexico.[4] Its recovery as a byproduct in the concentration of copper ores was begun in the United States by the Utah Copper Co. in 1936 from the Bingham deposit; it had already been accomplished in Mexico at Cananea in 1933. The Nevada Consolidated Copper Corporation became a molybdenum producer in 1937 from the Chino (Santa Rita) property in New Mexico, and in 1938 the Miami Copper Co. at Miami, Ariz., entered the field. These three producers supplied 24 percent of the 1942 production of molybdenum. The Bingham deposit is second only to Climax as a producer of molybdenum.

The molybdenum content of the various porphyry-copper deposits is quite variable. At Miami, the content is reported as 0.009 percent MoS_2; at Bingham [5] it is 0.04 percent; and at Chino the grade falls between these two.

Molybdenum is an accessory value at the Pine Creek tungsten mine of the United States Vanadium Corporation near Bishop, Inyo County, Calif. Lemmon[6], discussing the deposit, states that the ores are mainly disseminated in contact-metamorphosed limestones. Molybdenite and powellite [$Ca(Mo,W)O_4$] are the molybdenum minerals. The crude ore averages 0.5 percent MoO_3 and has a maximum of 2 percent MoO_3. Burwell [7] has described the metallurgical

problems in treating the ores, and Partridge [8] has given a brief history of the property.

At Tiger, Ariz., Mammoth-St. Anthony, Ltd., carries on a unique operation involving the only commercial production of molybdenum from wulfenite ($PbMoO_4$) in the United States. The molybdenum is in a complex ore which also carries values in gold, silver, lead, and vanadium. The recovery process employed is described as follows in a communication from J. L. Fozard, general manager, Mammoth-St. Anthony, Ltd. (slightly abridged):

> Smelting in a reverberatory furnace of oxide concentrates (which have been mixed with soda ash and coke) yields a lead bullion containing the bulk of the gold and silver; a small amount of matte carrying lead, copper, gold, and silver; and a molybdenum-vanadium rich slag, which is treated at the plant.
>
> The slag is hand-sledged, crushed, and ground wet in a rod mill. This solution contains the bulk of the vanadium and molybdenum that was in the slag. After suitable filtering, part of the solution is evaporated by smelter waste heat to the dry sodium molybdate-sodium vanadate salt; the remainder of the solution is used in the separation of the molybdenum from the vanadium.
>
> In the salt plant, the currently made salt, stored salt, and salt solution are mixed, the amount of stored salt to be used being determined from the specific gravity of the solution. This mixture is agitated for 8 hours. The molybdenum of the solid salt goes into solution, and the vanadium of the solution is precipitated. The product is filtered, the residue being the vanadium shipping product, which assays 20–25 percent V_2O_5 and less than 2 percent MoO_3. The filtrate is then agitated with lime and calcium chloride for 2 hours. This material is filtered. The residue is a low-grade molybdate-silicate precipitate, which is stored for future re-treatment. The filtrate is treated with calcium chloride, and a high-grade calcium molybdate is precipitated, filtered, dried, sacked, and shipped.

EXPLORATION AND DEVELOPMENT

In 1942 the Defense Plant Corporation purchased the Urad mine, 10 miles from Empire in Clear Creek County, Colo., from theVanadium Corporation of America. The Government agency was reported to have expended $110,000 in the purchase and to have authorized the further expenditure of $250,000 for development of the property by the Molybdenum Corporation of America, designated as operators. Production is scheduled to begin sometime in 1943. The Urad mine was a producer during World War I, having shipped several hundred thousand pounds of molybdenite concentrates in 1918 and 1919. Operations were suspended in 1919, and the mill was dismantled by the Vanadium Corporation of America, which acquired the property from the Primos Chemical Co.

No molybdenum has been mined commercially in Alaska, according to P. S. Smith,[9] who summarized details on geology, mineralogy, and exploration of 41 occurrences of molybdenum minerals scattered through that Territory. Field work was performed on the Muir Inlet molybdenum deposit by the Geological Survey, and exploratory investigations were carried on by the Bureau of Mines; the latter agency also examined the Shakan deposit, Prince of Wales Island.

CONSUMPTION AND USES

Since July 1941 the Bureau of Mines has conducted for the War Production Board (and its predecessor, Office of Production Management) monthly studies of production and consumption of molybdenum

and molybdenum products. Responses from consumers of molybdenum products indicate that, of the total consumption (exclusive of scrap) of over 22,000 short tons of molybdenum in 1942, approximately 63 percent was consumed as molybdenum oxide (roasted molybdenite), 24 percent as ferromolybdenum, 12 percent as calcium molybdate, and the remaining 1 percent as metal or as one of the molybdenum chemicals. Monthly consumption of molybdenum in primary products increased from about 1,300 tons in January 1942 to 2,200 tons in December. Ninety-five percent of all the molybdenum (including scrap) was used in the production of steel ingots and castings, 3 percent in iron castings, and 2 percent in minor uses such as pigments and colors, welding rods, etc.

An important step toward stretching available supplies of molybdenum and other critical steel-alloying metals was taken through adoption of specifications for NE (National Emergency) steels to replace the standard (SAE) steels. These alternate steels effect savings of critical metals through employment of leaner mixtures. The first specifications announced by the War Production Board in March 1942 included the Mn–Mo, Ni–Cr–Mo, and C–Mo steels. Revisions were made subsequently to meet changing conditions in supply of the metals involved. All but two of the compositions employing more than a maximum of 0.25 percent Mo were deleted.[10] Special attention was devoted to combining recoverable Ni, Cr, and Mo from scrap with small quantities of virgin metals, which led to introduction of two series containing 0.08 to 0.15 and 0.15 to 0.25 percent Mo, respectively.[11]

IMPORTS AND EXPORTS[12]

Molybdenum ore and concentrates were imported during 1941 and 1942. Total imports in 1942 amounted to 755,950 pounds (molybdenum contained), valued at $554,232, compared with only 4,300 pounds in 1941 (value $2,898). Molybdenum in other forms has not been imported since 1939, when 26,347 pounds contained in ferromolybdenum were received in the United States.

Molybdenum ore and concentrates exported from the United States, 1941–42, by countries[1]

Country	1941			1942		
	Pounds		Value	Pounds		Value

WORLD PRODUCTION

Canada.—Most of the molybdenum produced in Canada during 1942 came from Quebec, but small amounts were also obtained from British Columbia and Ontario.

The Moss mine [13] of the Quyon Molybdenite Co. is in Onslow Township (Pontiac District), Que., about 33 miles west of Ottawa. The molybdenite is disseminated, generally as small flakes, through a granitic mass. From 1916 to early 1919, concentrates containing 765,091 pounds of MoS_2 were produced, and the property was the world's leading individual molybdenite producer. In 1938 development was revived. Ore reserves were estimated at 30,000 tons containing 0.53 percent MoS_2 in 1941. A 150-ton mill and smelter were built in that year, and roasted molybdenite (molybdenum oxide) briquets are the shipping product.

Siscoe Metals, Ltd., took over operation of a property in La Corne Township (Abitibi District), near Amos, Que., for the Wartime Metals Corporation, a Canadian Government agency. The mine was dewatered to the 250-foot level, and a 150-ton mill was started. The ore is reported to grade somewhat less than 0.5 percent MoS_2, and reserves were given as 40,000 tons in old reports.

In Preissac Township (Abitibi District), about 400 miles northwest of Quebec City, the Dome Exploration Co., located a molybdenite deposit in an area in which unsuccessful efforts were made during World War I to develop commercial ore bodies. Eardley-Wilmot,[14] describing the deposits in this area, states that they are mostly fissure-vein types. Drilling in 1942 indicated an ore zone at least 400 feet long and 200 feet wide, with an average width of 30 feet. The grade ranges from 0.245 to 1.188 percent Mo, and the average is approximately 0.92 percent. The company was awarded a substantial contract by the Canadian Government and at the end of 1942 was proceeding with construction of roads, camps, and a 500-ton mill. Production is considered a likelihood by the spring or summer of 1943.

The Phoenix property of the Zenith Molybdenite Corporation, Ltd., in Bagot Township, Renfrew County, Ont., is to be operated by the Wartime Metals Corporation. A small production was realized from this property during World War I. The mill will be rehabilitated and operated as a custom plant for the district.

Other molybdenum deposits, too numerous to mention, in Quebec, Ontario, and British Columbia were under investigation.

French Morocco.—The Azegour molybdenite deposit,[15] 50 miles southwest of Marrakech, in western Morocco, was first noted about 20 years ago. Small shipments were made in 1929, 1930, and 1932. A 100-ton mill was erected by the Société Le Molybdène in 1933. The mill heads were stated to average 1.08 percent MoS_2 and 0.05 percent Cu. In 1941, von der Weid [16] published a monograph on the deposit.

Azegour is unusual in being one of the few contact metamorphic

Digitized by Google

molybdenite deposits in which there are commercial quantities of ore. The molybdenite occurs almost exclusively in garnetized limestones near the contact with granitic intrusions. The ore mineral is localized in interstices of the garnet rocks and in fractures.

According to statistics given by von der Weid the concentrates shipped from 1932 to 1938, inclusive, averaged 82.4 percent MoS_2, and the total content of molybdenum was 516.5 metric tons. It was reported in the press that in 1939 the output was about 250,000 pounds of molybdenum. "Small amounts" were said to have been exported in 1942.[17]

Manchuria.—Discovery of molybdenum at the Yangchiachantze properties of the Manchuria Lead Mining Co. in Chinchow Province was reported in 1939. The deposit was described as having a vein "several yards wide and about 100 yards long," with a metal content of 0.5 percent. In 1942 there appeared a news item [18] to the effect that as a result of intensified exploitation of the molybdenum deposits at Mienchiatzu and operation of a large "ore preparing and refining plant" the company was providing "equivalent to one-tenth the world's production" and hoped soon to be second to Climax.

Norway.—For some years before 1934, Norway was the second-largest molybdenum producer in the world. Since then, as far as available official statistics show, Mexico has occupied this rank. However, it was claimed recently that "Norway's production * * * in 1940 was 900 tons (fine)."[19] This figure indicates that in 1940 Norway again ranked second.

The Knaben deposits, 40 miles east of Stavanger, are the principal sources of production. Molybdenite occurs in veins and disseminated in granitic rocks in a zone several kilometers long and a few hundred meters wide. The ore mined in 1940 averaged 0.2 percent MoS_2, according to Quittkat,[20] who described the milling process.

Early in March 1943 it was reported than an R. A. F. attack on the Knaben mill had damaged, and probably destroyed, the whole plant.[21]

United States	666	World production and developments	670
Production in 1942	666		

SUMMARY

World production of vanadium ores is limited almost entirely to four countries—United States, Peru, Northern Rhodesia, and South-West Africa. The United States displaced Peru as the leading producer in 1941 and increased its lead in 1942 to supply over 50 percent of the total world output. All important sources of vanadium ore are controlled by the United Nations. However, vanadium is also recovered as a byproduct from other ores and raw materials. Significant among the other sources are certain iron ores and crude oils. The Axis countries apparently must rely on such sources, especially iron ores, and Germany is said to fulfill its requirements for vanadium in this manner. In the United States, vanadium ores have been supplemented with phosphate rock and imported vanadium-bearing flue dust to meet increased wartime needs. Titaniferous magnetite may yield future additions, and greatly increased exploitation of phosphate rock for its vanadium content is imminent.

Domestic shipments of vanadium ore in 1942 surpassed the record established in 1941 by 77 percent. More than 90 percent of the output comes from the Colorado-Utah region.

Salient statistics of the vanadium industry in the United States, 1940–42

	1940	1941	1942
Ores and concentrates (vanadium contained):			
Mine shipments—pounds	2,162,916	[1] 2,513,051	4,439,130
Value [2]	$1,044,100	[1] $1,179,500	$2,468,100
Mill products [3] (vanadium contained):			
Produced—pounds	1,548,133	1,853,655	2,655,784
Shipped—do	1,204,102	2,052,886	2,508,632
Value [2]	$2,350,500	$3,968,800	$4,890,800
Ore, concentrates, and vanadium oxide:			
Imports—short tons	22,551	12,323	18,246
Vanadium contained—pounds	2,574,951	2,138,608	2,422,376
Value	$1,216,705	$1,012,991	$1,274,483
Exports—short tons	[4]	28	37
Vanadium contained—pounds	[4]	25,462	22,140
Value	[4]	$63,213	$86,218
Vanadium-bearing flue dust:			
Imports—short tons	[5]	[5]	312
Vanadium contained—pounds	[5]	[5]	154,028
Value	[5]	[5]	$29,545

WAR REGULATIONS

The War Production Board placed vanadium deliveries under allocation on December 20, 1941 (Order M–23–a). Melting of vanadium was made subject to approval of the melter's schedule in an amendment to Order M–23–a on June 23, 1942. This amendment also lowered the limit of unrestricted deliveries of vanadium from 50 to 10 pounds per month. A further amendment, issued December 26, defined vanadium as including ores and concentrates, primary vanadium compounds, vanadium alloys, and waste products (such as flue dust); ferrovanadium producers are exempt from melting restrictions and may freely acquire vanadium-bearing raw material; no authorization is required for melting 10 pounds of vanadium or less per month.

MARKET AND USES

The nominal price of 27½ cents per pound of V_2O_5 contained has been quoted for vanadium ore since early in 1925, but there is a market by grades among mill operators. The average value of shipments, estimated from data collected by the Bureau of Mines, was 31 cents per pound in 1942, and prices as high as 50 cents were reported in sales to Metals Reserve Co. agencies. Vanadium pentoxide (technical grade) was priced at $1.10 per pound of V_2O_5 contained, and ferrovanadium was sold for $2.70 to $2.90 per pound of V contained.

Vanadium is generally extracted from ores and concentrates, the first stage of recovery being completed in the production of vanadium pentoxide (85 to 90 percent pure). This product is consumed largely as a raw material in the manufacture of ferrovanadium but also has a wide variety of applications, especially in chemical industries.[1] Ferrovanadium, containing 35 to 40 percent V in the normal domestic grades, is the principal means of introducing vanadium into tool steels and high-strength iron and steel forgings. The Bureau of Mines estimates that over 80 percent of the vanadium consumed is in the form of ferrovanadium. Figures of the War Production Board indicate that more than 60 percent of the total vanadium consumption is in tool steel, whereas nonmetallurgical uses absorb only 1 to 2 percent.

UNITED STATES

PRODUCTION IN 1942

The center of domestic vanadium-ore mining is in the Colorado-Utah region. A small output is realized in Arizona and Nevada, and vanadium-bearing phosphate rock is mined in Idaho. Production seems assured in the near future from the phosphate rock deposits in Wyoming, and recovery of vanadium from magnetite concentrates produced in New York is a possibility.

The Colorado-Utah vanadium-ore region is an area comprising southwestern Colorado, southeastern Utah, and extending into northern Arizona. In recent years production has been limited to only a small part of the vanadium-ore region. Burwell [2] states that

[1] Alexander, J., Vanadium and Some of Its Industrial Applications: Chem. and Ind., vol. 48, 1929, pp. 871–878; 895–901.

Digitized by Google

during 1942 the principal producers, in cooperation with Government agencies, prepared for the development of other areas by building roads (of which 300 miles were completed), by opening ore-purchasing depots to provide a market for small producers, and by establishing plants near the newly opened areas to treat ore from hitherto untouched and former marginal deposits. The principal problem in mining is the interpretation of ore structures and, corollary thereto, the following of the irregular course of the deposits.

The deposits occur principally in the Morrison formation, but those at Rifle and Placerville, Colo., are found in the Entrada sandstone. According to Fischer: [3]

> * * * The deposits in the Entrada sandstone are commonly referred to as the "vanadiferous sandstone deposits," or "roscoelite deposits," as they contain only a trace of uranium. The deposits in the Morrison formation, on the other hand, are generally referred to as the "carnotite deposits," a term that has been carried over from the time of the earlier operations, when carnotite was the desired mineral because of the uranium and radium it contained. These deposits, however, contain several times as much vanadium as uranium, and the bulk of the vanadium is apparently in the same mineral form as in the deposits in the Entrada sandstone.
>
> The principal vanadium mineral is micaceous, and it has heretofore been thought to be roscoelite, the vanadium mica; but, as a result of recent X-ray studies * * * it is now thought to belong to the imperfectly understood hydrous-mica group of clay minerals. * * * The vanadium-bearing hydrous mica forms an aggregate of minute flakes, coating the sand grains. * * * Where the sandstone was more strongly mineralized, the pore spaces are completely filled with the vanadium mineral. This mineral imparts to the sandstone a gray or greenish-gray color, which darkens as the vanadium content increases.

The "carnotite ores" were mined principally for their uranium and radium content from 1911 to 1923, but some vanadium was recovered as a byproduct from 1915 to 1923. With the advent of other sources of radium, mining of these ores was greatly curtailed. Since 1937 the production has been resumed on a larger scale, now primarily for the vanadium content. The "roscoelite ores" were mined from 1909 to 1923 and 1925 to 1932, and since 1941.

The principal producers in 1942 were the United States Vanadium Corporation, which operates mills at Uravan and Rifle, Colo., and is the operator for the Metals Reserve Co. of a mill at Durango, Colo., and the Vanadium Corporation of America, with a mill at Naturita, Colo., and one operated for the Metals Reserve Co. at Monticello, Utah. The Rifle, Durango, and Monticello mills began producing vanadium oxide during 1942. Ores were also milled by North Continent Mines, Inc., at Cedar, Colo.; the Nisley & Wilson Vanadium Mill at Gateway, Colo.; and the Blanding Mines Co., Blanding, Utah.

In Arizona vanadium is recovered as sodium vanadate from complex (gold-silver-lead-molybdenum-vanadium) ore by Mammoth-St. Anthony, Ltd., at Tiger, Pinal County. The vanadium-ore minerals are vanadinite and descloizite. The process employed in recovering calcium molybdate and sodium vanadate is described in the chapter of this volume on Molybdenum.

Since 1923 the Anaconda Copper Mining Co. has mined phosphat rock at Conda, Caribou County, Idaho.[4] The rock, which is said to

contain 0.3 percent V_2O_5 (or about 0.16 percent V),[5] is treated at the Anaconda reduction works in Montana for the manufacture of superphosphate. It was not until 1941 that a byproduct recovery of the vanadium in the form of "red cake" (vanadium oxide containing approximately 90 percent V_2O_5) was effected. The fundamental recovery process was evolved by the A. R. Maas Chemical Co. and patented in 1935, according to F. C. Bowman of that company,[6] who states that "The Anaconda Copper Company adopted the process and after considerable developmental research put it into commercial operation in 1941." The process in use now is summarized briefly as follows:[7]

> The rock is treated with sulphuric acid, primarily for the purpose of leaching out the phosphoric acid. At the same time, approximately 65 percent of the vanadium contained in the rock goes into solution together with the phosphoric acid. This is precipitated as phospho-vanadic acid by treating the solution with sodium chlorate. The yellow crystalline precipitate is separated by settlement. It contains phosphorus, iron, alumina, lime, and other impurities. By treatment with milk of lime and soda ash under carefully controlled conditions, the vanadium is obtained in a substantially pure sodium vanadate solution, from which vanadium pentoxide, V_2O_5, is precipitated by the addition of sulphuric acid.

EXPLORATION AND DEVELOPMENT

The vanadium resources in phosphate rock are attaining greater potential significance. The Federal Geological Survey announced in February 1943 that, as a result of studies begun in 1939, millions of tons of ore containing small percentages of vanadium had been discovered in southeastern Idaho and southwestern Wyoming in the same phosphate rock formation now mined at Conda, Idaho. The particular achievement was the discovery of an extensive shale horizon in the Phosphoria formation carrying commercial quantities of vanadium in a very finely divided state. The Bureau of Mines participated in the exploratory work in the Sublette and Afton areas of Wyoming and the Paris-Bloomington area of Idaho during 1942 and is continuing its investigations in 1943. Research on the metallurgical treatment of the ore has also been carried on to determine the best method of extracting vanadium. The Metals Reserve Co. contracted with the Homestake Mining Co. to develop these vanadium deposits. The work is being done by the Wyodak Coal & Manufacturing Co., subsidiary of the Homestake company.

An interesting mining development during 1942, which may affect the vanadium supply of the United States, was the reopening of the Lake Sanford titaniferous magnetite deposits in the Adirondack region of New York by the National Lead Co. The project, known as the MacIntyre development, was undertaken to provide a new domestic source of titanium for the manufacture of pigments. The ores of this region have long been known to contain small percentages of vanadium,[8] but no commercial recovery has been made to date. Hagar [9] describes the ore body at Lake Sanford as consisting of "irregular fine-grained masses of mixed ilmenite and magnetite distributed in an anorthosite country rock." The vanadium is contained

in the magnetite; the content is 0.35 percent.[10] The plans call for mining about 4,500 short tons of ore daily, with a production of 900 tons of ilmenite concentrate and 1,800 tons of magnetite concentrate. The magnetite and ilmenite are associated in a mechanical mixture, according to Hagar, permitting ready separation of the ore minerals.

The recovery of vanadium from the Lake Sanford magnetite was the subject of an investigation by the Bureau of Mines, the National Lead Co., and the University of Minnesota.[11] According to the report on the investigation:

(p. 2) It appears that most of the vanadium in this ore can be recovered in pig iron, which can be blown in a converter to produce a slag containing vanadium in amounts suitable for the production of ferrovanadium. * * *

(p. 23) A recovery in the metal of 87.3 percent of the vanadium was obtained during the operation of the experimental blast furnace on burdens composed of iron ore and titaniferous sinter containing 11.1 percent TiO_2 and 0.26 percent vanadium. Approximately 4 percent of the vanadium was lost in the slag. These results show that the oxides of vanadium are reduced readily under blast-furnace conditions.

The potential annual recovery of vanadium from the Lake Sanford ore has been estimated at about 3,000,000 pounds in the form of ferrovanadium.[12]

Wood, Joseph, and Cole [13] call attention to several recent foreign experiments on methods of recovering vanadium from iron ore and slags. A more extensive review of recent literature on vanadium recovery, emphasizing especially Russian and German metallurgical work on these sources of vanadium, was prepared during 1942 by Lathe [14] of the National Research Council of Canada.

IMPORTS AND EXPORTS [15]

In 1941 imports of vanadium ore and concentrates were obtained almost exclusively from Peru and totaled 24,645,686 pounds with a vanadium content of 2,138,608 pounds. Other sources, especially South-West Africa, augmented the supply of vanadium in 1942, as is shown in the following table.

Vanadium ore and concentrates and vanadium-bearing flue dust imported for consumption in the United States in 1942, by countries

Country	Ore and concentrates			Vanadium-bearing flue dust		
	Pounds		Value	Pounds		Value
	Gross weight	Vanadium content		Gross weight	Vanadium content	
Canada				370,217	73,074	$15,554
Curaçao (N. W. I.)				125,303	11,818	9,835
Peru	31,610,284	2,053,399	$979,037	128,903	69,136	4,156
South-West Africa [1]	4,881,984	368,977	295,446			
	36,492,268	2,422,376	1,274,483	624,423	154,028	29,545

All exports of vanadium ore and concentrates in 1942 went to Canada. The total was 73,542 pounds (vanadium contained, 22,140 pounds), valued at $86,218.

WORLD PRODUCTION AND DEVELOPMENTS

Canada.—Canada does not produce any vanadium ores. According to Bateman,[16] small amounts of vanadium are recovered from soot and ashes collected from oil-burning vessels. The Metal Controller's Office presented a schedule of prices for vanadium-bearing petroleum soot. The schedule is quoted as this source of vanadium has gained some importance recently. The prices in Canadian currency, per pound of contained V_2O_5, f. o. b. Castleton, N. Y., by grades, follow: 5 to 7.9 percent V_2O_5, 43 cents; 8 to 10.9 percent, 46 cents; 11 to 13.9 percent, 49 cents; 17 percent and more, 54 cents.[17] Bateman stated that open-hearth slags of the Dominion Iron & Steel Co. at Sydney, Nova Scotia, contain enough vanadium (which he believes could be recovered) to meet Canadian needs, if necessary. The slags [18] are derived from Newfoundland (Wabana) iron ores used at Sydney. Vanadium was found in titaniferous magnetites examined by the Ontario Department of Mines in Papineau Township, Ont., during 1942. Grab samples assayed 0.63 to 0.99 percent V_2O_5. [19]

Germany.—Extensive research on recovery of vanadium from iron ores has been reported from Germany. It is generally assumed that the vanadium supply is derived from this source, but no positive knowledge of the output is indicated in published reports. Planner [20] states that German ores yield the greater part of that country's requirements of over 10,000 tons of vanadium annually, produced in the form of an iron-vanadium alloy by conversion of slag. The stated requirements are striking, as they exceed the entire world production of vanadium from ores and probably from all other raw materials; also, they represent a very marked increase over German consumption in earlier years. Zieler [21] reported that the consumption was estimated at about 150 metric tons of vanadium contained in ferrovanadium in 1934, and at 300 to 400 tons in 1937, and that a considerable increase was indicated in 1938.

Northern Rhodesia.—Vanadium is the principal product, in terms of value, now recovered from the Broken Hill lead-zinc-vanadium deposit.[22] The ores, occurring in a series of steeply dipping lenses replacing dolomite, are roughly zoned, the rich vanadium ores being developed largely in the broken ground between the massive oxidized ores and the dolomite, as well as in fissures. The vanadium-ore

minerals are descloizite and vanadinite. Vanadium-bearing laterite, in many places containing 3 percent V, is also mined at the surface, The export of vanadium ore was begun in 1921. Facilities for producing fused vanadium oxide were put into operation in 1930. The ore treated in the vanadium plant averaged 1.41 percent V in 1939. Proved reserves in June 1940 at Broken Hill were 2,400,000 tons of oxidized ore containing 0.83 percent V_2O_5, or approximately 11,200 tons of vanadium. The Camarnor vanadium deposit, 20 miles northeast of Broken Hill, has been worked on a small scale only.

Peru.—Peru has been an important source of vanadium for many years. From 1938 to 1940, inclusive, and in several earlier years it was the largest producing country in the world. Principal source is the famed Mina Ragra of the Vanadium Corporation of America in the Andes near Ricran, Department of Junin. The vanadium ore occurs associated with asphalt and was first prospected as a source of fuel for the Huaraucaca smelter, but because of the sulfur content the mine was abandoned. In 1905, Rizo Patron, the smelter manager, discovered that this carbonaceous material was rich in vanadium, and steps were taken immediately to explore the property. Patronite, the vanadium sulfide (named after its discoverer), was abundant in the deposit but is now virtually mined out. The remaining ore is largely a red calcium vanadate which carries up to 50 percent V_2O_5, occurring in pockets and filling cracks or fissures in the shales. The ore is surface-mined from an open pit 650 meters long and 360 meters wide. Operations at the reduction plant include roasting, lixiviation, precipitation, filtering, and drying. In the past, concentrates averaging 15 percent V and ores including ashes averaging 4 to 5 percent V were exported, but it is planned to ship only higher-grade concentrate or precipitate with about 50 percent V content, to reduce the volume of shipping space required as well as freight charges. During 1942 a new treatment plant with a daily capacity of 200 tons of lower-grade ore was under construction, which, with the 80-ton plant already in operation, would permit doubling the output. Total ore reserves are estimated at somewhat less than 500,000 tons, consisting of 27 percent "veta madre" ore with 4 percent V, 40 percent "broza" ore with 0.9 percent V, and the remainder flotation and leached tailings and a small tonnage of oxide dumps averaging 0.7 percent V. The total vanadium content of this ore is said to exceed 6,000 tons.[23] A minor source of vanadium is the vanadiferous ashes derived from asphaltites; the largest deposits of this material are at Yauli, Department of Junin, where the asphaltite was used at one time as a coal substitute. The V_2O_5 content of the ash may be as high as 20 percent, but ordinarily it is much lower.[24]

South-West Africa.—Vanadium deposits of distinctive character are numerous in the Otavi Mountains of northern South-West Africa over a distance of some 60 miles between Uris and Berg Aukas.[25]

Digitized by Google

The first discovery was made at Tsumeb-West before World War I. After the war, search revealed many other occurrences, including that of Abenab in 1921, which proved to be one of the largest vanadium deposits in the world.

The copper-lead-zinc vanadates of the Otavi region occur in a thick, folded series of dolomites and limestones. Cavities ("sandsacks") in the country rock are filled with lumps of vanadates (mainly descloizite and cuprodescloizite), blocks of silicified dolomite, and red dune sand. The vanadates also encrust the dolomite blocks and walls of the cavities and penetrate as veinlets into the adjacent country rock. Some of the "sandsacks" are the weathered outcrops of ore-bearing pipes or sink holes, but others show no ore below the cavities. The ore bodies are highly variable in size. The Abenab pipe deposit is 200 by 120 feet at the surface, but the Uris is only 50 to 60 feet across and the majority are considerably smaller. The crude ore contains 2 to 3 percent V_2O_5.

Abenab and another deposit operated by the Southwest Africa Co. are now producing 300 tons of concentrates (averaging 18 percent V_2O_5) a month. In earlier years this company produced also at Baltika, but the deposit was exhausted in 1939. The depletion of present reserves may be counteracted by further development work or discoveries. The Otavi Minen- und Eisenbahn-Gesellschaft formerly operated the Tsumeb and Uris deposits. The company suspended operations in September 1940. Subsequently it was reported that the South African Government would assume operation of the company properties. Shipments were made in 1942, and the production rate is reported as 40 to 60 tons per month of 10.5-percent V_2O_5 concentrates. The Karavatu deposit is apparently the source of present output from the Otavi holdings.

The total output from South-West Africa since 1920 has been over 65,000 short tons of concentrates or more than 6,500 tons of contained vanadium.

Venezuela.—The soot of Venezuelan oils, especially from Maracaibo, contains as much as 34 percent V_2O_5.[26] During 1942 several thousand pounds of soot were shipped by oil companies, which obtain the product from smokestacks of their tankers and power plants.

TUNGSTEN

By H. W. Davis

SUMMARY OUTLINE

	Page		Page
Summary	673	Domestic production	675
Salient statistics	673	Foreign trade	681
Government exploration	674	Consumption and uses	682
Prices	675	World production	682

SUMMARY

Stimulated by greatly increased needs for tungsten in the military program and by higher prices, production of tungsten concentrates and high-grade sorted ore in the United States, despite the shortage of labor at many mines, reached a new peak in 1942. The labor shortage was relieved somewhat when the Army released some soldiers for work in tungsten mines. Domestic production was 9,433 short tons (60 percent WO_3 basis) in 1942, or 40 percent more than in 1941, the previous record year. Virtually the entire gain was contributed by California, Idaho, and Nevada, as output in all other producing States (except Texas) declined. The combined production in California, Idaho, Nevada, and Texas increased 54 percent over 1941; that in the remaining producing States decreased 37 percent. Three operators—one each in California, Idaho, and Nevada—accounted for 70 percent of the total 1942 output. The Yellow Pine mine in Idaho, which made its initial production in 1941, rose to be the second-largest producer in the United States in 1942. Probably more prospecting and developing were done on domestic tungsten-ore deposits during 1942 than in any other single year. New mills were completed at several mines.

Salient statistics of tungsten ore and concentrates in the United States, 1941–42

	1941		1942	
	Short tons, 60 percent WO_3	Value	Short tons, 60 percent WO_3	Value
Domestic production	6,746	(1)	9,433	(1)
Shipments from domestic mines	6,567	$9,223,726	9,333	$13,508,266
Imports:				
General (receipts)	13,820	(1)	15,851	(1)
For consumption	12,107	11,231,313	14,715	(1)
Stocks at consumers' plants, Dec. 31	2,527	(1)	3,590	(1)

[1] Figures not available.

Digitized by Google

Notwithstanding shipping difficulties, receipts of imported ore and concentrates increased 15 percent over 1941 to an all-time high of 15,851 short tons (60 percent WO_3 basis) in 1942. Of the 1942 total, Argentina supplied 17 percent, Bolivia 43 percent, and China 30 percent.

Consumption of tungsten ore and concentrates also reached a new peak in 1942 and amounted to 18,300 short tons (60 percent WO_3 basis), a gain of 5 percent over 1941.

To aid further in stimulating the domestic production of tungsten, the Metals Reserve Co. announced on April 22, 1942, that its domestic price policy of $24 per dry short-ton unit of WO_3 would remain in effect until December 31, 1943. In November 1942 the price was increased to $30 a unit.

Figure 1 shows trends in domestic shipments, imports, and prices of tungsten ore and concentrates since 1915.

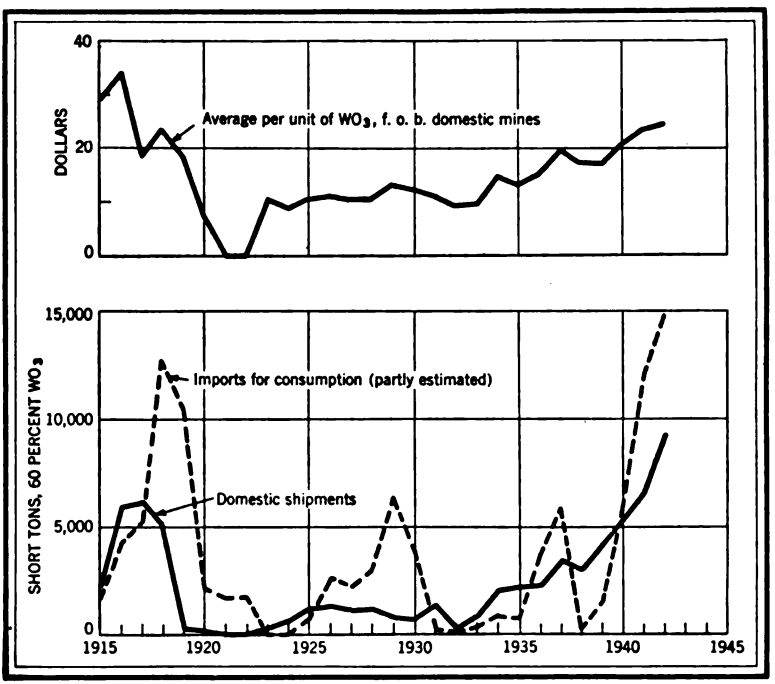

FIGURE 1.—Trends in domestic shipments, imports, and average price of tungsten ore and concentrates, 1915–42.

GOVERNMENT EXPLORATION

Continuing its search for strategic minerals, the Bureau of Mines investigated deposits of tungsten in Idaho, Colorado, Nevada, Wyoming, New Mexico, and Alaska during 1942. Exploration was continued at the Ima mine in Lemhi County, Idaho, in the Boulder County (Colo.) field, and at the Riverside mine at Hyder, Alaska. A substantial tonnage of low-grade ore was indicated by trenching and diamond drilling at the Tungstonia deposit in White Pine County, Nev. Surface trenching and diamond drilling on the properties of the North Tem Piute Mining & Development Co. and Tem Piute Mining Co. in Lincoln County, Nev., indicated a fairly large tonnage of low-

Digitized by Google

grade ore. At the property of the Tungsten Mining Co. at Cherry Creek, White Pine County, Nev., five scheelite lenses were explored by trenching and diamond drilling that indicated a substantial tonnage of low-grade ore. In New Mexico, exploration work was done on the Iron Mountain tungsten deposits in Sierra County. In the West Tintic district, Utah, diamond drilling and underground work indicated that a small production of tungsten ores will be available. The Romur tungsten property in Fremont County, Wyo., presents the possibility of opening up an entirely new tungsten-mining district. Exploration was begun on this property in November 1942. A limited program of trenching, sinking shallow shafts, and drifting underground by the Bureau has indicated that this district may contribute a large tonnage of tungsten.

The Geological Survey continued and expanded examination of domestic tungsten deposits as part of its program of investigations of strategic-mineral deposits. Altogether, over 100 separate areas, including more than twice that number of individual deposits, were examined, many of them at the request of various other Government agencies. This work was distributed over all of the Western States, Alaska, and, in the latter part of the year, northern Mexico. A number of the more promising deposits were studied in detail, and some other districts previously examined were reviewed. In several districts, Survey geologists collaborated with the Bureau of Mines on exploration projects; among these were Boulder County, Colo.; Seven Devils, Idaho; Cherry Creek, Tempiute, and Tungstonia, Nev.; Darwin, Calif.; and Hyder, Alaska. Reports on earlier work at Silver Hill, Wash., and in the Nightingale district, Nev., were published in 1942.

PRICES

Quotations on tungsten ore and concentrates were steady throughout 1942. According to the Engineering and Mining Journal, Chinese, Bolivian, and Portuguese ore was quoted at $24 a short-ton unit of WO_3, duty paid, and domestic scheelite, in carlots, delivered, at $26 a short-ton unit. The buying price of Metals Reserve Co. for domestic ore and concentrates from "eligible" producers was $24 a short-ton unit until November 19, 1942, when it was increased to $30. The average price for the domestic concentrates and high-grade sorted ore shipped in 1942, as reported to the Bureau of Mines, was $24.12 a short-ton unit of WO_3.

DOMESTIC PRODUCTION

Spurred by the need for tungsten to successfully prosecute the war, production of tungsten concentrates and high-grade sorted ore in the United States gained 40 percent over 1941 to reach an all-time high of 9,433 short tons (reduced to an equivalent of 60 percent WO_3) in 1942. The ore was obtained from a large number of widely scattered operations in Alaska, Arizona, California, Colorado, Idaho, Montana, Nevada, Texas, Utah, and Washington. However, California, Idaho, and Nevada supplied 93 percent of the total output, and three operators (one in each of these States) produced 70 percent of the United States total. California, which displaced Nevada as the principal producing State in 1940, maintained its rank in 1942.

In addition to the output of 9,433 tons of concentrates and high-grade sorted ore, a considerable tonnage of low-grade concentrates,

Digitized by Google

which require further milling, was produced in 1942; these concentrates have been or will be shipped to the re-treatment plant of Metals Reserve Co. at Salt Lake City, Utah, which was expected to begin operating in April 1943. The resultant high-grade concentrates recovered from this material will be included in later production and shipment figures.

Tungsten ore and concentrates produced and shipped in the United States, 1941–42, by States

State	Produced				Shipped from mines

Tungsten ore and concentrates shipped from mines in the United States, 1938–42

Year	Quantity		Reported value f. o. b. mines		
	Ore and concentrates, 60 percent WO_3 (short tons)	Tungsten content (pounds)	Total	Average per unit of WO_3	Average per pound of tungsten
1938	3,044	2,897,036	$3,161,498	$17.31	$1.09
1939	4,287	4,080,024	4,402,182	17.11	1.08
1940	5,319	5,062,199	6,576,318	20.61	1.30
1941	6,567	6,249,945	9,223,726	23.41	1.48
1942	9,333	8,882,403	13,508,266	24.12	1.52

Alaska.—At the Riverside mine near Hyder, virtually the entire 1942 operating season was devoted to treating slimes from previous operations, from which a small tonnage of concentrates was recovered and shipped. According to J. H. Scott, owner and operator of the mine, these slimes were difficult to treat, but toward the end of the season the metallurgical difficulties were solved. In the mill, 14 additional flotation cells and other equipment were installed. Some underground work was done in the mine, which brought about the discovery of good ore.

Arizona.—Production of tungsten concentrates in Arizona was 181 short tons averaging 69.23 percent WO_3 in 1942, compared with 251 tons averaging 66.90 percent WO_3 in 1941. Shipments were 192 tons averaging 68.44 percent in 1942 and 246 tons averaging 67.49

Digitized by Google

percent WO_3 in 1941. The output comprised scheelite, wolframite, huebnerite, and ferberite. By far the largest output came from the Boriana mine near Yucca, Mohave County, where wolframite and scheelite concentrates averaging 68.74 percent WO_3 were recovered from milling a 1.05-percent WO_3 ore in 1942. The mining and milling of tungsten ores at the Boriana mine were described recently by Munds.[1] The remainder of the output, which was produced at a number of widely scattered operations, came chiefly from the Tungsten Reef mines in Cochise County, Chloriding and Diff claims in Mohave County, and Morning Star claim in Pinal County.

California.—California maintained its rank as the principal tungsten-producing State in 1942. Shipments of tungsten concentrates (virtually all scheelite) from California totaled 3,334 short tons averaging 62.68 percent WO_3 in 1942, compared with 2,629 tons averaging 59.42 percent WO_3 in 1941. Although tungsten concentrates were shipped from a large number of widely scattered operations, six producers—the Atolia Mining Co. (in San Bernardino County), and the United States Vanadium Corporation, Tungstar Corporation, West Coast Tungsten Co., El Diablo Mining Co., and Bishop Tungsten Corporation (all in Inyo County)—accounted for 3,051 tons, or 92 percent of the State total. The bulk of the remainder was shipped from the Garnet Dike mine in Fresno County; Tungsten City and Victory mines in Inyo County; Stardust and Tungsten Chief mines in Kern County; Quigley mine in Madera County; and Big Jim, Dinuba, and Posey mines in Tulare County.

Production of tungsten concentrates in California was 3,324 short tons averaging 63 percent WO_3 in 1942, compared with 2,747 tons averaging 59 percent WO_3 in 1941. Of the 1942 total, Inyo County supplied 79.9 percent; San Bernardino 14.2 percent; Tulare 1.1 percent; Kern 1.0 percent; and Fresno, Mono, Madera, and Tuolumne Counties together 1.4 percent; the source of 2.4 percent was not reported. The largest producer in California, as well as in the United States, during 1942 was the United States Vanadium Corporation, which operated the Pine Creek mine near Bishop and, in addition, milled ore and tailings from other properties in California and in Nevada; the concentrates recovered from milling ore and tailings from Nevada have been credited in the statistics to that State. The new 1,300-ton concentrating and chemical plant of the company was put into operation the latter part of 1941, and as a consequence production of concentrates increased 77 percent in 1942 over 1941. The milling plant has been described by Burwell.[2] Development done in 1942 at the mine included 16,954 feet of diamond drilling, 2,677 feet of raises, 1,082 feet of crosscuts, and 2,926 feet of drifts. Mine development at the close of 1942 comprised adits and tunnels with sublevels and raises connecting approximately 12,000 feet in main levels and 8,000 feet in sublevels.

The Tungstar Corporation, operating the Tungstar mine near Bishop, completed at a cost of $135,000 a new aerial tramway, having an inclined length of 11,800 feet and a capacity of 100 tons in 8 hours, to transport ore from the mine to the mill. The tramway has been described by Engineering and Mining Journal.[3] The company also

Digitized by Google

did 1,300 feet of tunneling and drifting into an ore body containing about 50,000 tons of ore averaging 0.75 to 1 percent WO_3. Work was carried on by sinking below tunnel level of the original ore body, where about 20,000 tons of 1.5- to 2-percent WO_3 ore were developed. The company operated its mill on a one-shift basis for 9 months but was idle 3 months because of its inability to transport ore from the mine. Consequently production of concentrates declined markedly in 1942.

The Adamson mine near Bishop was being developed by Panaminas (Inc.) in 1942. A plant was under construction, two adits were started at the 1,300-foot level, and a jib-back tram to the upper ore bodies was being installed.

During 1942 development was done at many other properties in California, and several new mills were completed, but lack of space precludes giving detailed information.

Colorado.—Production of tungsten concentrates in Colorado declined to 492 short tons averaging 46 percent WO_3 in 1942 from 810 tons averaging 48 percent WO_3 in 1941, and shipments dropped to 491 from 787 tons. Virtually the entire ouptut was ferberite from Boulder County, the greater part of which came from operations of the Wolf Tongue Mining Co. and the Vanadium Corporation of America. The bulk of the remainder came from operations of George H. Teal & Associates, S. W. Shattuck Chemical Co., W. L. & S. H. Tanner, Tom Walsh, and Boulder Tungsten Mills (Inc.). Most of the concentrates produced by George H. Teal & Associates and Boulder Tungsten Mills were shipped to the re-treatment plant at Salt Lake City, Utah, for further milling. A comparatively small quantity of huebnerite was produced in 1942 in San Juan County and a little ferberite in Summit County.

The Wolf Tongue Mining Co. did considerable core drilling (from surface and underground), surface trenching, drifting, and crosscutting but found no additional ore bodies. Core drilling was done at the Dorothy mine of George H. Teal & Associates, and two ore bodies were found to have commercial value. At the Pueblo Belle mine of the S. W. Shattuck Chemical Co. the shaft was sunk from 160 to 360 feet, but no ore was found below the 320-foot level; at the 200-foot level the drift was being extended eastward. Boulder Tungsten Mills (Inc.) completed a mill in mid-1942, which treated ore from its own mines and purchased ore; the company began unwatering and retimbering eight mines.

Idaho.—Production of tungsten concentrates in Idaho increased phenomenally to 2,389 short tons averaging 53.55 percent WO_3 in 1942 from 1,291 tons averaging 30.81 percent in 1941. Shipments of high-grade concentrates were 2,366 tons averaging 53.45 percent in 1942, compared with 1,269 tons averaging 31.03 percent WO_3 in 1941. In addition, 7,023 tons of low-grade flotation concentrates averaging 10.51 percent WO_3 were produced in 1942, of which 5,984 tons averaging 10.56 percent WO_3 were shipped to the re-treatment plant at Salt Lake City, Utah, for further milling. These low-grade concentrates have been omitted from the 1942 statistics, but the resultant high-grade concentrates recovered will be included in later figures.

The chief tungsten-producing mine in Idaho and second-largest in the United States was the Yellow Pine near Stibnite, in Valley County, where tungsten production was begun by the Bradley Mining Co. in August 1941. In 1942 this mine produced and treated 96,861

Digitized by Google

short tons of scheelite ore averaging 2.61 percent WO_3, which yielded 2,276 tons of high-grade concentrates (52.98 percent WO_3) and 6,905 tons of low-grade concentrates (10.48 percent WO_3). Most of the low-grade concentrates were shipped to the re-treatment plant at Salt Lake City for further milling. About four-fifths of the output in 1942 came from underground workings. During 1942 two Hardinge ball mills (making a total of 4), additional flotation cells (making a total of 12), and auxiliary equipment were installed; as a result, production in 1943 is expected to be double that in 1942, although the grade of ore will be lower. In 1943 at least three-fifths of the output will be from open-pit operations. The Yellow Pine mine has been described recently by Bradley, Mecia, and Baker.[4]

Production at the Ima mine in the Blue Wing district, Lemhi County, was 36 percent less than in 1941. Methods and costs of concentrating huebnerite ores at the Ima mine have been described by Dice.[5]

Tungsten became an important product of the Atlanta Group of claims near Atlanta, Elmore County, in 1942. These claims, operated by Talache Mines (Inc.), are Idaho's chief gold producers, and exploration has revealed tungsten ore in commercial quantities; however, the ore is of low grade in tungsten and could not be mined without its gold and silver content to supplement its tungsten value. One section of the company mill was converted to treat tungsten ore during 1942; 13,675 short tons of scheelite ore averaging 0.15 percent WO_3 were produced and treated, yielding 118 tons of concentrates averaging 12.26 percent WO_3, most of which were shipped to the re-treatment plant at Salt Lake City for further milling.

Montana.—Small quantities of scheelite were recovered from a waste dump in Park County and as a byproduct of placer mining in Powell County in 1942.

Nevada.—Nevada maintained its rank as the second-largest tungsten-producing State in 1942. Production and shipments of concentrates (reduced to an equivalent of 60 percent WO_3) were 3,135 and 3,052 short tons, respectively, compared with 2,316 and 2,289 tons, respectively, in 1941. The greater part of the production was scheelite concentrates from operations of the Nevada-Massachusetts Co. and affiliated companies, which operate mills at Mill City, Golconda, and Toulon. Smaller but important producers of concentrates in 1942 were: Nevada Scheelite, Inc., operating the Leonard mine in Mineral County; Tungsten Metals Corporation, operating the Scheelite Chief, Oriole, Everitt, and Silver Bell mines in White Pine County; Lincoln Mines, Inc., operating the Tem-Piute mine in Lincoln County; M. G. L. Mining Corporation, operating the M. G. L. mine in Pershing County; and Getchell Mines, Inc., operating mines in Humboldt County. The contentrates produced by Getchell Mines, Inc., have not been included in the 1942 statistics because they require further milling at the Salt Lake City re-treatment plant. Of the other smaller mines producing concentrates in 1942, the largest were the Star in Elko County, Defense Tungsten in Humboldt County, Desert Scheelite and Gunmetal in Mineral County, and Black Mule and Tungsten Minerals in White Pine County.

During 1942 Nevada Scheelite, Inc., made about 1,000 feet of new

Digitized by Google

drifts, opened several large stopes from 40 to 80 feet wide, put finger raises through from the 100-foot level to the surface, and installed a new crushing plant.

A flotation plant was put into operation in August 1942 by Getchell Mines, Inc., and during the remainder of the year 21,675 short tons of scheelite ore averaging 0.394 percent WO_3 were treated, yielding 537 tons of concentrates averaging 12.69 percent WO_3. The ore treated came from the company mines in Humboldt County and from the Richmond mine, near Winnemucca, also in Humboldt County but operated by W. C. Rigg, who also has developed the Rose Creek mine in Pershing County to the productive stage. Development at the Getchell mines included 195 feet of drifts, 90 feet of crosscuts, and 97 feet of raises. Van Voorhis has described the mining and milling of tungsten ores by Getchell Mines, Inc.[6]

The M. G. L. mine, in Pershing County near Nixon, which has been under development for some time, made its initial output in August 1942 and during the remainder of the year produced and treated 10,233 short tons of scheelite ore, which yielded 73 tons of concentrates averaging 68 percent WO_3. The mine is provided with a modern concentrating plant.

Development was done at many other properties in Nevada in 1942, among which were the Cherry Creek and Canary Yellow in White Pine County, Star in Elko County, Silver Dyke in Mineral County, Defense Tungsten in Humboldt County, and Red Top and Red Ant in Churchill County, but lack of space precludes giving detailed information.

The tungsten deposits of the Nightingale district have been described by Smith and Guild.[7]

Texas.—A small quantity of scheelite was produced by the Moore Mining Co. in 1942 near Sierra Blanca in Hudspeth County, where a small mill was erected.

The scheelite occurrences in Gillespie County have been described recently.[8]

Utah.—Production of tungsten (all scheelite) in Utah was 33 short tons averaging 54 percent WO_3 in 1942, compared with 46 tons averaging 39 percent WO_3 in 1941. Shipments were 30 tons averaging 57 percent WO_3, compared with 44 tons averaging 41 percent WO_3 in 1941. Although production came from operations in Beaver, Box Elder, Juab, and Tooele Counties, two-thirds came from the Lone Pine mine in Box Elder County. Most of the remainder came from the Star Dust mine in Tooele County and the Massae mill in Box Elder County.

In addition to the 33 short tons of high-grade ore and concentrates produced in 1942, a small tonnage of ore was mined at several properties and shipped to the re-treatment plant of Metals Reserve Co. at Salt Lake City, which was expected to begin operating in April 1943.

Washington.—Shipments of tungsten concentrates from Washington were 73 short tons averaging 35.48 percent WO_3 in 1942, compared with 121 tons averaging 33.91 percent in 1941. Most of the pro-

duction again came from the Germania mine near Fruitland, Stevens County, where the General Electric Co. worked over surface float and tailings to recover 19 tons of wolframite concentrates averaging 65 percent WO_3 and 45 tons of wolframite jig concentrates averaging 14 percent WO_3. Comparatively small quantities of wolframite concentrates were produced by James Keeth, Industrial Tungsten Corporation, Roy B. Greene, and W. H. West in Stevens County, and by the Zellweger Mining Co. in Okanogan County. W. H. West installed a jig mill at his mine in 1942, and the Zellweger Mining Co. had a small jig mill partly installed at the close of the year.

The tungsten deposits at Silver Hill, Spokane County, have been described by Page.[9]

FOREIGN TRADE[10]

Domestic production of tungsten is inadequate for requirements, and the United States imports both tungsten concentrates and products, chiefly the former. Receipts of imported ore and concentrates established a new high in 1942 and amounted to 15,085,793 pounds (tungsten content), equivalent to 15,851 short tons of 60 percent WO_3. Although ore and concentrates were received from 15 foreign countries in 1942, three—Bolivia (43 percent), China (30 percent), and Argentina (17 percent)—supplied 90 percent of the total.

Imports in 1942 for consumption amounted to 14,004,257 pounds (tungsten content), equivalent to 14,715 short tons of 60 percent WO_3; Bolivia, China, and Argentina supplied 47, 28, and 16 percent, respectively, of the total. In addition, 6,115 pounds of tungsten in concentrates were imported from Argentina (duty free) for smelting, refining, and export.

Tungsten ore and concentrates imported into the United States in 1942, by countries, in pounds

Country	General imports[1]		Imports for consumption[2]	
	Gross weight	Tungsten content	Gross weight	Tungsten content

The duty on tungsten ore or concentrates is 50 cents per pound on the metallic tungsten contained therein. This is equivalent to $7.93 per short-ton unit.[11]

Exports of tungsten ore and concentrates from the United States are insignificant and amounted to only 15,714 pounds in 1942. From July to December 1941 exports were 2,616 pounds; exports of tungsten ore and concentrates before July 1, 1941, are not separately recorded.

Imports of tungsten metal were 4,435 pounds (tungsten content), compared with 36,793 pounds in 1941. No ferrotungsten, tungsten carbide, tungstic acid and other compounds of tungsten, or combination containing tungsten or tungsten carbide were imported in 1942.

Exports of metal, wire, shapes, and alloys other than ferrotungsten were 313,223 pounds in 1942, compared with 195,762 pounds in 1941. In 1942 exports of ferrotungsten were 297,108 pounds, and from July to December 1941 they were 5,180 pounds. Exports of sodium tungstate, tungstic acid, and tungstic oxide were 1,419, 39, and 11 pounds, respectively, in 1942; they were 58, 10, and none, respectively, from September to December 1941. Exports of ferrotungsten before July 1 and of sodium tungstate, tungstic acid, and tungstic oxide before September 1, 1941, were not separately recorded.

CONSUMPTION AND USES

Consumption of tungsten ore and concentrates in the United States was about 18,300 short tons (60 percent WO_3 basis) in 1942, compared with 17,500 tons in 1941. Of the total consumed in 1942, about 68 percent was converted to ferrotungsten, the form in which most of the tungsten is introduced into steel. However, high-purity tungsten concentrates are charged directly to the steel bath, and 17 percent of the total was so used in 1942. Metallic tungsten required about 10 percent of the total tungsten ore and concentrates consumed in 1942, and various tungsten chemicals absorbed the remainder (5 percent).

The chief use of tungsten, according to quantity, is in the manufacture of cutting tools, the majority of which are made of high-speed steel containing about 18 percent tungsten, 4 percent chromium, and 1 percent vanadium—commonly known as "18–4–1." Smaller quantities of tungsten are used in numerous other types of high-speed steels. Molybdenum-tungsten high-speed steels (which contain 1 to 2 percent tungsten and 5 to 10 percent molybdenum) are being used successfully for many applications of tungsten high-speed steels. Other important uses of tungsten are in armor-piercing projectiles, stellite and tungsten carbide cutting tools, magnet steels, austenitic valve steels and valve seats, and erosion-resisting gun liners. Minor amounts of tungsten are used in lamp and radio-tube filaments, X-ray targets, and electrical contact points. Tungsten salts are used in the chemical, pigment, and tanning industries.

WORLD PRODUCTION

Because of restrictions on the publication of statistics by many governments, a record of recent production in many countries is not available.

[11] A unit, as applied to tungsten ores, is 1 percent of a ton of tungsten trioxide (WO_3). Thus, a short-ton unit is 20 pounds of WO_3 or 15.86 pounds of tungsten (W).

Argentina.—Argentina ranks second to Bolivia as a producer of tungsten in South America. Output comes principally from the Provinces of San Luis and Córdoba; much smaller amounts are produced in San Juan, Catamarca, Mendoza, and La Rioja. Production was 2,008 and 1,564 metric tons (66 percent WO_3), respectively, in 1942 and 1941. Exports were 1,636 metric tons averaging 66 percent WO_3 (all to the United States) in 1942.

Australia.—The principal sources of tungsten in Australia are mines at Grassy, King Island; Storey's Creek, Tasmania; Hatch's Creek and Wauchope, Northern Territory; Banks Island, Torres Strait; and Wolfram Camp, Queensland.

The King Island Scheelite Co. is the Commonwealth's largest producer. During the year ended October 31, 1942, it milled 32,200 long tons of ore, which yielded 242 tons of concentrates; in 1941 it milled 29,250 tons of ore and re-treated 18,870 tons of tailings, which yielded 204 and 17 tons, respectively, of concentrates. The company plans to erect a new concentrating mill to treat 20,000 tons of ore monthly.

Bolivia.—Bolivia is the largest tungsten producer in South America. Most of the deposits are in the Departments of La Paz, Oruro, Potosí, and Cochabama. The principal mineral is wolframite with some scheelite. Output (as indicated by exports) was 5,606 and 4,353 metric tons (60 percent WO_3 basis), respectively, in 1942 and 1941.

Canada.—An intensive search for tungsten ores was under way in Canada during 1942, and as a consequence many deposits were found. The distribution of the ores has been discussed by Eardley-Wilmot.[12] Output of tungsten concentrates was 218 short tons (62 percent WO_3) and 41 tons (51 percent WO_3), respectively, in 1942 and 1941. Output was from six provinces and the Northwest Territories in 1942, but most of it was from British Columbia, Northwest Territories, and Ontario.

Nigeria.—The tungsten deposits of Nigeria have been described in considerable detail by Haag.[13]

Peru.—Production of tungsten in Peru is relatively small, but since 1937 it has increased progressively and amounted to 370 metric tons (60 percent WO_3 basis) in 1942. Exports of ores and concentrates were 337 metric tons in 1942, compared with 322 tons in 1941; figures for WO_3 content of the exports are not available. The principal productive mines are in the Departments of La Libertad, Ancash, Puno, and Huancavelica. There was considerable activity in developing and expanding production in 1942. The Cia. Minera Tauca, after delays caused by poor mill construction, began producing concentrates in August 1942 at Ogapita, Department of Ancash. At Pasto Bueno, Department of La Libertad, the Banco Minero del Peru installed a tungsten concentrator of 30 to 40 tons daily capacity to handle custom ores from small mines in that region. A 150-ton gold-tungsten plant for treating oxidized gold ores containing tungsten was being constructed at the Tentadora mine near Lircay, Department of Huancavelica. In the Mundo Nuevo area, Department of Ancash, power plant and drilling equipment were being installed preliminary to erection of a small gravity tungsten concentrator.

SUMMARY

As the Nation fought through the first full year of its greatest war, aluminum became one of the most important metals in the war machine. Without the vast tonnages of the vital white metal, produced by a rapidly expanding domestic industry, the unprecedented number of bombing and fighting planes now giving air superiority to the United Nations over large areas of the earth's surface could not have been produced. Production (521,106 short tons) and consumption (588,522 tons) of primary aluminum in 1942 advanced 69 and 94 percent over 1941. The annual rate of production at the end of 1942 had risen to 720,000 tons, and the total output in 1943 should substantially exceed 900,000 tons. Imports from Canada are expected to aggregate about 225,000 tons in 1943, making the total available supply of primary aluminum more than 1,125,000 tons. Secondary production in 1943 is estimated at an additional 293,000 tons.

Highlights of the industry in 1942 included the following: Eight Government-owned, Aluminum Company-operated reduction plants were begun or completed; the Olin Corporation became the third domestic producer of aluminum; two large Government-owned alumina plants were built, and one of them began operations in the fall; and plans were made for constructing lime-soda-sinter units at the four large Bayer-process plants. In May 1943, construction of the new lime-soda-sinter units was well under way; production had begun at the new Government-owned alumina plant at Baton Rouge, La.; and operations were scheduled to start in the Government-owned alumina plant at Salt Lake City, Utah.

Recovery of secondary aluminum increased 86 percent in 1942. Imports and exports of crude and semicrude aluminum in 1942 increased 736 and 419 percent, respectively, compared with 1941.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Digitized by Google

Production (2,768,343 short tons) and consumption (2,820,525 tons) of bauxite in 1942 increased 176 and 46 percent, respectively, compared with 1941. As with aluminum production, the large output of bauxite in 1942 will be dwarfed by the 1943 production, estimated at nearly 7,000,000 short tons. Imports of bauxite, reduced by a shortage of ships and enemy submarine action, are estimated at about 1,000,000 short tons in 1943. Of the total estimated 1943 supply of nearly 8,000,000 tons, estimated requirements will take about 5,550,000 tons, and the remainder will be stocked by the Government and private industry. The allocation order, effective August 1, 1942, to conserve and direct the distribution of bauxite and alumina assures that the most essential uses are met by allocating the bulk of the high-grade bauxite to the alumina and abrasive industries.

In 1942 imports of bauxite (990,323 short tons, 76 percent of which came from Surinam) decreased 21 percent from 1941, while exports (dried equivalent) rose 35 percent. Of the domestic and foreign bauxite consumed, the alumina industry used 79 percent; chemical, 9 percent; abrasive and refractory, 11 percent; and other industries, 1 percent. Compared with 1941, the aluminum industry increased its consumption of bauxite approximately 67 percent; abrasive and refractory, 19 percent; and all other, 14 percent; whereas bauxite used in the chemical industry decreased 22 percent. Domestic ore was equivalent to 59 percent and imports to 41 percent of the total bauxite consumed. Shipments from Arkansas mines comprised 94 percent of the total domestic production, and output in Georgia, Alabama, and Virginia rose substantially above that in 1941. The average value actually received for all grades of ore shipped in 1942 dropped 9 percent from 1941.

World production of bauxite is believed to have increased 24 percent and of aluminum 35 percent in 1942. United Nations output of aluminum and bauxite in 1942 was estimated at 59 and 65 percent of the world totals and will be even larger in 1943.

BAUXITE

PRODUCTION

A new all-time high was recorded in 1942 when bauxite production (mine shipments converted to a dried-equivalent basis) in the United States increased 176 percent in quantity and 141 percent in value over 1941. Production rose 187 percent in Arkansas, 46 percent in Alabama, 410 percent in Georgia, and 58 percent in Virginia. A small production was recorded from Mississippi; no bauxite was produced in that State during 1941.

Mines in Saline and Pulaski Counties, Ark., produced 94 percent of the total domestic output in 1942. American Cyanamid & Chemical Corporation operated the Rauch, Heckler, and England mines in Pulaski County and the Townsend, Ozark No. 24, Globe No. 28, Cargill, Fletcher, Quapaw, and Gates (Consolidated) mines in Saline County. Mining was done underground by the room-and-pillar method at the Rauch Lease, Heckler, Globe No. 28, and Gates properties; all other mining was open-pit. Large-scale stripping was carried on by dragline at the England, Cargill, and Fletcher properties, and mining began in September. The company's West Bauxite processing plant was idle in early 1942, but dried bauxite for the Republic Mining & Mfg. Co. during the latter part of the year. The Bierman property was developed by Consolidated Chemical Industries, Inc., and a shaft was sunk in 1942 preparatory to underground mining in 1943. Crouch Mining Co., Inc. (owned by General Abrasives Co.), mined and calcined ore from its Young mine, developed in 1941, solely for the abrasive industry. Dixie Bauxite Co., Inc., continued operations on its Dixie No. 2 underground mine and began underground mining at its Dixie No. 3 property. The calcining mill was dismantled and sold to Bauxite Co. of Alabama in the fall of 1942, and Dixie Bauxite Co. was engaged solely in producing high-grade bauxite for the aluminum industry. Dulin Bauxite Co., Inc., produced ore from its Reichardt mine throughout the year and stripped overburden from a large area. The Harley open-pit mine began operations late in May and closed temporarily during November and December 1942, and additional development was done on the Thorpe lease, which will be mined in 1943. The old Consolidated-Harris mine was reopened and some ore removed in December. A calcining kiln was installed by Dulin Bauxite Co., Inc., during 1942 to calcine high-grade ore for the abrasive industry. Hardin & Prewitt Bauxite Co. began mining in December from its open-pit property in Pulaski County for the Metals Reserve Co. The Porocel Corporation erected a new plant at Berger, Pulaski County, to manufacture an isomerization catalyst made from low-iron activated bauxite impregnated with anhydrous aluminum chloride for use in the production of high-octane aviation gasoline.

Republic Mining & Mfg. Co. (subsidiary of Aluminum Co. of America), the principal domestic producer, extended its previous open-pit mining operations; open-pit mining was done in secs. 10, 14, 15, 16, 27, T. 2 S., R. 14 W., Saline County, and major overburden

Digitized by Google

stripping jobs were in progress during 1942 in other sections. A large new drying plant more than doubling Republic's drying capacity was constructed during 1942 at Bauxite and put into operation early in 1943; maximum production is expected by August 1943. Reynolds Mining Corporation operated its Covington and Hurricane underground mines near Brooks, Saline County, in 1942, after sinking shafts through difficult ground in early fall, and during the latter half of 1942 conducted extensive stripping operations at the Sherrill property in Pulaski County. Sweet Home Bauxite Co. began operations at its open-pit Sweet Home mine in Pulaski County in May and continued mining throughout the year. Sweet Home Mining Co. stripped its Hurricane Creek property in Saline County and began mining early in 1943. Victory Bauxite Co. opened its Weiss open-pit mine in Pulaski County in November and continued mining until April 1943; the company will open a new property in 1943 in Saline County. New Arkansas producers in 1943 will include the Bauxite Drilling & Testing Co., S. E. Evans Construction Co., and a new company to operate the Maner Graham and Billy Bridewell properties.

Bauxite shipped from mines in the United States, 1938–42, by States

State and year	Short tons					Value, f. o. b. mine, as shipped
	Crude	Dried	Calcined	Total		
				As shipped	Dried-bauxite equivalent	
Alabama and Georgia:

[1] Includes small quantity of activated.
[2] Includes Virginia.
[3] Includes Mississippi and Virginia.
[4] Includes sintered.

The production of bauxite in Alabama increased during 1942, but the percentage increase recorded was lower than in any other State. Bauxite Co. of Alabama, Barbour Bauxite Co., Republic Mining & Mfg. Co., Floridin Co., and D. M. Wilson Bauxite Co. were active in the Eufaula area in Barbour and Henry Counties. New driers were built in early 1943 by Bauxite Co. of Alabama and Barbour Bauxite Co. to dry ore for the chemical industry. J. C. Hebble ceased mining near Asheville, St. Clair County.

At Andersonville, Sumter County, Ga., American Cyanamid & Chemical Corporation increased production at its Thig Pen mine and operated an oil-fired drying kiln nearby, and Benjamin Easterlin shipped a small quantity of ore before abandoning his mine late in 1942. Republic Mining & Mfg. Co. opened a drying plant in Floyd

Digitized by Google

County and produced a small amount of ore from its Booger Hollow mine. H. G. Bradhaw and General Ore Co. also produced small quantities of ore from the Hermitage area in Floyd County. Bethlehem Co. mined for a short time at its Irwinton and Toomsboro mines and is planning to construct a small drier in Wilkinson County.

Republic Mining & Mfg. Co. continued to mine near Spottswood, Augusta County, Va., operating the Allen, Harris, and Lightner properties. J. W. Adams mined a small tonnage of ore from the Flora mine in Kemper County, Miss., in the fall of 1942.

A canvass of producers, conducted by the Bureau of Mines in November 1942, indicated that 1943 bauxite production will approach 7,000,000 short tons. It is estimated that known domestic reserves of what are at present considered commercial grades of bauxite will not last more than 3 years at the expected 1943 depletion rate. In realization of the precarious condition of bauxite reserves, the Bureau of Mines and the Federal Geological Survey in the fall of 1941 initiated an extensive drilling and exploration program in all States where bauxite deposits were known or thought to occur.

Stratigraphic studies in the Coastal Plain had shown that all known bauxite deposits in the province were associated with the Midway-Wilcox contact, and reconnaissance work was done along this horizon from Georgia to Texas by the Geological Survey in an effort to locate new areas in which bauxite deposits might be expected. Some areas that warranted further exploration were found, but the greatest value of the preliminary work was to eliminate large areas from further consideration. The largest Geological Survey party worked in Arkansas in cooperation with the Bureau of Mines drilling project and collected and assembled geologic information, made aerial and subsurface maps of selected districts, made drilling recommendations, and furnished other geological advice. In the eastern Gulf Coastal Plain drilling recommendations were made for three areas in Mississippi, two in Alabama, and two in Georgia. All the known deposits in the Appalachian Valley were examined and drilling recommendations were made for two districts in northwestern Georgia, two in northeastern Alabama, and one in Tennessee. Cooperation was also extended by the Survey in locating and logging drill holes and in furnishing information for the war minerals reports on bauxite prepared by the Bureau of Mines.

In Arkansas the Bureau of Mines covered 1,400 square miles in Pulaski and Saline Counties by geophysical surveys in 1942 and drilled 573 holes, with an average discovery of more than 10,000 long tons of bauxite per hole. The total footage drilled was 134,900, and 208 or 36 percent of the holes were in bauxite. Eight deposits were delimited by drilling and an estimated 3,650,000 long tons of marketable ore indicated. Reduced to a mined and dried basis, the total commercial ore discovered was approximately 1,912,500 long tons or 2,142,000 short tons.

At Eufaula, Ala., and Andersonville, Ga., Bureau drilling has disclosed considerable tonnages of marketable bauxite, and further exploration is being actively carried on in these areas. Initial prospecting disclosed 929,000 long tons of marketable ore, which on a mined and dried basis is approximately 670,000 long tons or 750,000 short tons. Drilling at Rock Run, Ala., and Chattanooga, Tenn., during 1942 gave disappointing results, disclosing only very small tonnages of marketable ore.

Digitized by Google

Stocks of bauxite on hand at mines and processing plants on December 31, 1942, totaled 294,337 short tons (dried bauxite equivalent) compared with 171,023 on December 31, 1941. Stocks at consumers' plants increased from 593,849 tons at the beginning of the year to 959,082 at the end. Metals Reserve Company stock piles contained 479,207 tons at the end of 1942.

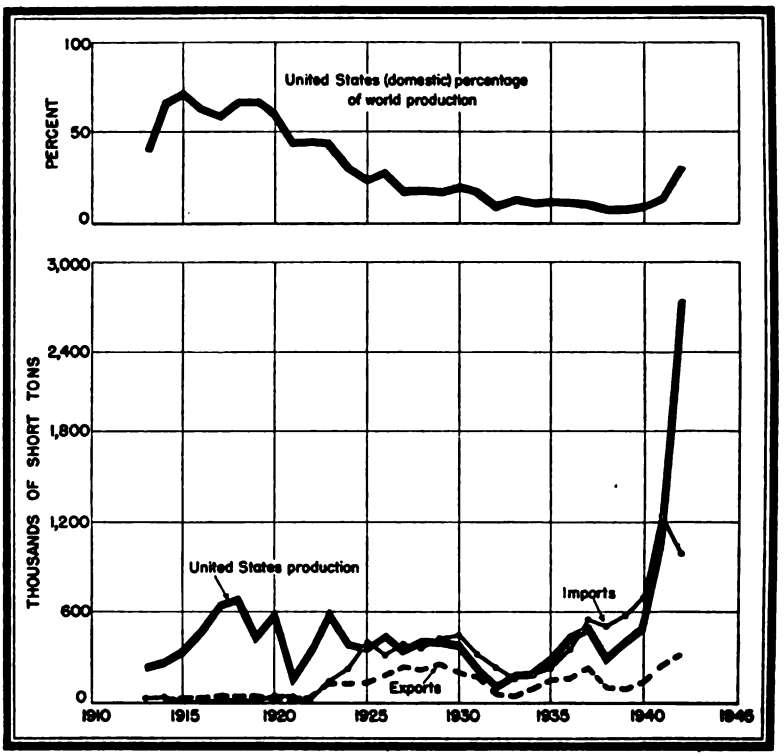

FIGURE 1.—Trends in production, imports, and exports of bauxite, 1913–42.

CONSUMPTION

Actual domestic consumption of bauxite (as determined by special monthly consumer surveys conducted by the Bureau of Mines for Federal war agencies) totaled 2,820,525 short tons (dried bauxite equivalent) in 1942 and compared with a consumption of 1,928,052 tons in 1941. The 1941 figure includes exports to Canada, as virtually all bauxite shipped there during that year was destined to American-owned abrasive plants for the manufacture of crude abrasives returned to the United States for final manufacture and consumption. The 1942 figure includes bauxite shipped to abrasive plants in Canada but does not include approximately 100,000 tons of dried ore shipped to the Canadian aluminum industry. Consumption of the 2,820,525 tons was as follows: Alumina industry, 2,229,157 tons; chemical, 256,479; abrasive (including refractories), 302,557; and cement, oil refining, steel, and ferro-alloy industries, 32,332 tons. Consumption

Digitized by Google

of bauxite "as shipped" totaled 2,742,573 tons and consisted of 430,486 tons of crude bauxite, 2,124,450 tons of dried, 180,337 tons of calcined and sintered, and 7,300 tons of activated ore. Of the bauxite consumed (dried equivalent basis), 41 percent was foreign and 59 percent domestic ore. The alumina industry used 94 percent and the chemical industry 4 percent of the foreign ore. About 2 percent of the foreign ore was employed in abrasives, cements, and other uses.

Apparent domestic consumption, shown in the table below, is presented from two different points of view; and apparent consumption within the United States does not correspond with the data above, inasmuch as the calculations are based upon "shipments" to domestic plants and do not consider fluctuations in consumers' stocks.

Shipments, imports, exports, and apparent consumption of bauxite in the United States, 1938–42, in short tons

[Dried-bauxite equivalent]

Year	Domestic shipments from mines and processing plants to industry			Imports	Exports	Apparent consumption within United States	Apparent consumption, including shipments to Canada for processing [1]
	Arkansas	Alabama and Georgia [2]	Total				
1938	308,088	19,323	327,411	510,376	101,182	736,605	819,800
1939	375,925	15,331	391,256	582,601	96,925	876,932	971,000
1940	490,107	[3] 12,995	503,102	705,098	134,462	1,073,738	1,200,600
1941	960,741	[3] 89,389	1,050,130	1,250,532	244,934	2,055,728	[3] 1,928,052
1942	2,588,637	[3] 153,663	2,742,300	990,323	329,477	3,403,146	[3] 2,820,525

[1] Includes exports to Canada, inasmuch as virtually all of this bauxite is shipped to American-owned plants in Canada for manufacture into crude abrasives reimported into the United States for final manufacture and consumption.
[2] Includes Virginia in 1940 and 1941 and Virginia and Mississippi in 1942.
[3] Actual consumption.

BY INDUSTRIES

The following table shows only shipments of domestic bauxite to consuming industries and excludes foreign ore.

Aluminum.—Actual consumption of bauxite by the aluminum industry increased approximately 67 percent over that in 1941 and comprised 79 percent of all the domestic and foreign ore used. The industry employed dried and undried ore from Alabama, Arkansas, Surinam, British Guiana, and Brazil. Estimated bauxite consumption in 1943 is expected to be about 118 percent above that in 1942.

Abrasive and refractory.—Manufacturers of crude aluminous abrasive pigs in Canada and the United States received approximately 19 percent more domestic bauxite in 1942 than in 1941, being consigned 6 percent of all the domestic ore shipped to industry. Except for a small quantity from British Guiana, all of the calcined and sintered ore employed came from Arkansas. The industry's 1943 ore requirements are expected to exceed those of 1942 by about 33 percent. The use of bauxite in refractories is combined with abrasives. In 1942 the consumption of special aluminous refractory products increased substantially over 1941 in the steel, glass, ship, and other industries.

Total value	$1,823,307		$2,448,038		$3,075,317		$6,155,714		$13,672,727	

[1] Includes crude, dried, calcined, and activated, 1938–42; and sintered, 1939–42.
[2] Includes some ore shipped to the abrasive and chemical industries.
[3] Includes 672,000 tons (584,640 dried equivalent) shipped to Metals Reserve Co. stock piles.
[4] Small quantity of bauxite shipped to makers of refractories probably included under "Abrasive."

Digitized by Google

Chemical.—The chemical industry consumed 22 percent less bauxite in 1942 than in 1941 and used 9 percent of all the domestic and foreign ore consumed. Shipments of domestic bauxite from mines and processing plants to the chemical industry increased 10 percent. Consumption by the industry in 1942 totaled 256,479 short tons of bauxite, but this includes ore used to make some aluminum chemicals other than those shown in the following table and does not include a large portion of the bauxite used in the manufacture of the alumina shown in the table. Ore used to make the aluminum salts and alumina shown in the table totaled approximately 306,880 tons. In addition to bauxite, producers of aluminum salts reported consuming 8,364 tons of alumina (calcined equivalent), 6,031 tons of primary and secondary aluminum, 19,637 tons of clay, and a relatively small quantity of beryl and chromite residue. Manufacturers estimated that their 1943 bauxite consumption will be 13 percent less than in 1942 (exclusive of a large part of the bauxite consumed in making alumina for the chemical and other industries).

Production and shipments of aluminum salts decreased 4 and 3 percent in 1942. Production of alumina increased 9 percent, but shipments decreased 7 percent. Of this alumina, only 14 percent was consumed by the producers of aluminum salts; the remainder was used in the manufacture of abrasives, refractories, petroleum products, spark plugs, glass, rubber, paints, and various other commodities.

Aluminum salts and alumina produced and shipped in the United States, 1941–42

[1] 147 pounds in 1941 and 50 pounds in 1942.

Early in 1943 the Torrance Aluminum Products Co. began producing sodium aluminate at a plant in Torrance, Calif. The aluminous raw material being used is fine aluminum dross from West coast reduction plants. In late 1942 and early 1943 the General Chemical Co. was changing from bauxite to clay as an aluminous raw material at all of its aluminum chemicals plants, a change of major importance as the company has been a large consumer of bauxite in past years. A central calcining plant is being built at Owensville, Mo., which will calcine Missouri diaspore and ship the product to all General Chemical Co. widely scattered aluminum-salts plants.

Other.—The use of thermally activated bauxite as an adsorbent and catalyst in the petroleum industry maintained about the same rate as in 1941 but is expected to expand substantially in 1943, as production of high-octane aviation gasoline and synthetic rubber increase. More bauxite was used in fluxing ferro-alloys and in high-early-strength aluminous cement. Consumption in the cement, steel and ferro-alloy, and oil-refining industries rose 14 percent above the quantity used in 1941, and it is estimated that 1943 bauxite needs will exceed 1942 use by 90 percent.

PRICES

In 1942 the average selling price, f. o. b. mines and processing plants, was $3.84 a short ton for crude (undried) bauxite, $4.51 for crushed dried bauxite, $11.97 for calcined bauxite, and $46.68 for activated bauxite. Values per long ton were as follows: $4.30 for crude, $5.05 for dried, $13.41 for calcined, and $52.28 for activated bauxite. The average value for all grades of domestic ores as shipped was $4.80 a short ton ($5.30 in 1941) or $5.38 a long ton ($5.94 in 1941). Nominal market quotations on domestic, chemical, crushed and dried bauxite rose from $7 to $8.50 a long ton in 1941 to $7.50 to $8.50 in 1942. The Metals Reserve Co. began purchasing ore in May 1942, for stock piling and for consumption in the new Hurricane Creek (Ark.) and Baton Rouge (La.) alumina plants. The price schedule, set up by the Metals Reserve Co. for purchasing bauxite, provides a base price of $4 a long ton for ore containing 50 percent alumina and 13 percent silica, and a system of penalties and bonuses.

FOREIGN TRADE

Imports of bauxite in 1942 dropped 21 percent from the peak year of 1941, whereas exports (dried equivalent) increased 35 percent. Of the 1942 imports, 748,642 short tons came from Surinam, 238,426 from British Guiana, 3,252 from Brazil, and 3 from Canada. By customs districts, importations were as follows: 892,291 tons to Mobile, 69,427 to New Orleans, 19,451 to Philadelphia, 9,149 to Massachusetts, 3 to Vermont, and 2 to New York. Of the 1942 exports, 251,509 short tons were classified as bauxite and other aluminum ores, and 40,362 tons as alumina and other bauxite concentrates. More than 99 percent of the exports went to Canada; only small quantities were shipped to Argentina, United Kingdom, Iran, Trinidad and Tobago, Australia, Mexico, Curaçao, Venezuela, Cuba, and the Dominican Republic.

Bauxite imported into and exported from the United States, 1938–42

ALUMINUM

PRODUCTION

Primary.—The production of 521,106 short tons of primary aluminum in 1942—69 percent more than the 309,067 tons produced in 1941—represented another all-time record for the aluminum industry. It was considerably more than the entire world production in 1937 but represented only about 50 percent of the ultimate annual production goal. The annual rate at the end of 1942 had risen to 720,000 tons, and the expected rate on December 31, 1943 (including all plants now operating, under construction, or approved), is estimated at approximately 1,147,000 tons. Actual domestic output in 1943 should total substantially more than 900,000 tons or more than the world production in 1940. The five aluminum-reduction plants of the Aluminum Co. of America and the five Defense Plant Corporation plants operated by the Aluminum Co. produced the larger part of the 1942 output. The Olin Corporation became the third producer of primary aluminum when it began operations at its plant in Tacoma, Wash., in 1942. Of the Aluminum Co. output from its privately owned plants, 39 percent was made at Alcoa, Tenn.; 23 percent at Vancouver, Wash.; 20 percent at Massena, N. Y.; 13 percent at Badin, N. C.; and 5 percent at Niagara Falls, N. Y. Of the output at Aluminum Co.-operated Defense Plant Corporation plants 31 percent

Digitized by Google

was produced at Massena, N. Y.; 25 percent at Mead, Wash.; 18 percent at Troutdale, Oreg.; 15 percent at Jones Mills, Ark.; and 11 percent at Los Angeles, Calif. The Listerhill (Ala.) plant of Reynolds Metals Co. supplied 55 percent of Reynolds' production, and the Longview (Wash.) plant the remaining 45 percent. The value of the aluminum shipped in 1942 averaged 14.62 cents a pound compared with 16.24 cents in 1941.

The second Government expansion program (of February 26, 1942) providing for an additional 320,000 tons of metal has not been increased since that date, although capacity estimates have been changed on the basis of performance so that the original privately owned capacity and the early expansion financed by private and Reconstruction Finance Corporation capital now totals about 474,000 tons; the first Government expansion, about 338,000 tons; and the second Government expansion, about 360,000 tons. On February 20, 1942, a contract was made between Defense Plant Corporation and the Aluminum Co. of America whereby the Aluminum Co. undertook to construct a 500,000-ton alumina plant at Baton Rouge, La., in addition to the 500,000-ton plant already approved at Hurricane Creek (Bauxite), Ark. A 150,000-ton addition to the Hurricane Creek plant was begun in February 1942; and recently, owing to the unexpectedly high production of metal per potline in the newer reduction plants, another expansion of 127,500 tons was announced for Hurricane Creek. The Kalunite, Inc., alumina plant at Salt Lake City, Utah, originally scheduled for 10,000 tons annual capacity, was expanded twice to 30,000 and finally to 36,000 tons.

All but one reduction plant in the first expansion program are essentially complete, and all plants in the second expansion program are partly constructed. Of a total of 36 potlines in the group owned by the Defense Plant Corporation and operated by the Aluminum Co. all but 14 were completed as of May 20, 1943. Two to four completed potlines in the new plants were idle during the latter part of 1942 and the early part of 1943 due to an acute alumina shortage. For this reason the alumina plants are being pushed toward completion under AA–1 priorities as rapidly as possible.

Bauxite importation problems became acute in the summer of 1942 owing to a shortage of cargo space and to an intensive submarine campaign in Caribbean waters. This situation caused a sharp drop in imports of high-grade South American ore, and more domestic ore of a considerably lower grade had to be used to keep the alumina plants going. Realizing this fact, and with shipping prospects growing steadily worse, the War Production Board, on advice from the National Research Council, approved lime-soda-sinter units at each of the four Aluminum Co.-operated alumina plants. Owing to delays, construction was not begun on these units until January and February 1943, but they are now proceeding under AA–1 priorities and will be in partial operation by September 1943.

In addition to the expansion of reduction and alumina plants there was a large increase, part in Government-owned and part in privately owned fabricating plants, of strong alloy-sheet capacity as well as forging, extrusion, rod and bar, and casting capacity. During early 1943 bottlenecks in the fabricating program in extrusions and rod and bar facilities constituted one of the main limiting factors in the ex-

pansion of aircraft production. This situation will be largely alleviated during the summer of 1943.

In 1942 the Aluminum Co. of America virtually completed its $250,000,000 privately financed expansion of alumina, aluminum-reduction, and fabricating capacity. In addition to company-owned expansion, the Aluminum Co. is building many plants for the Defense Plant Corporation which it will operate for the Government, among which are the following: Alumina plants at Baton Rouge, La. (500,000-ton annual capacity) and Hurricane Creek, Ark. (777,500 tons) aluminum-reduction plants at Massena, N. Y. (54,000 tons), Troutdale, Oreg. (72,000 tons), Los Angeles, Calif. (90,000 tons), Jones Mills, Ark. (72,000 tons), Mead (Spokane), Wash. (108,000 tons), Maspeth, L. I., N. Y. (144,000 tons), Burlington, N. J. (54,000 tons), and Modesto, Calif. (54,000 tons); sheet rolling mills at Spokane, Wash. (144,000 tons), and Chicago, Ill. (144,000 tons); extrusion and tubing plants at Cressona, Pa. (30,000 tons), and Phoenix, Ariz. (33,000 tons); forging plants at Cannonsburg, Pa. (38,700 tons), Newcastle, Pa. (10,600 tons), Vernon, Calif. (19,500 tons), and Monroe, Mich. (672,000 cylinder heads annually); plants for producing cast cylinder heads for air-cooled engines at Kansas City, Mo. (1,200,000 heads), and St. Paul, Minn. (600,000 heads); and a synthetic cryolite plant at Hurricane Creek, Ark. (9,000 tons).

After the refusal of the War Labor Board to allow a general wage increase in the plants of Aluminum Co. of America in the fall of 1942, the Aluminum Workers of America and the Aluminum Co. negotiated a wage adjustment applying to the plants at New Kensington, Detroit, Bridgeport, and Edgewater, which was subsequently allowed by the Board. During early December three wildcat strikes within a week interrupted production at the Detroit plant of Bohn Aluminum &

Digitized by Google

Brass Co. As the result of a week-long strike of the Mine, Mill, and Smelter Workers, Die Casting Division, Congress of Industrial Organizations, in die-casting plants of the Aluminum Co., the War Labor Board withheld the union's security clause for 60 days as a disciplinary measure. In January 1943 an unauthorized strike against rotating shifts took place in the New Kensington plant. Slowdowns and other labor difficulties that greatly curtailed production at the Cleveland plant of the Aluminum Co. were investigated in early February by a representative of the United States Army plant-protection service. The trouble continued, however, and developed into a walk-out, ending on February 26, 1943, after the War Labor Board ordered the discharge of 44 of the striking employees. Workers of the Republic Mining & Mfg. Co., the bauxite-mining subsidiary of Aluminum Co. of America, received a wage increase of 5 cents an hour retroactive to September 20, 1942, upon authorization by the War Labor Board in March. On April 21, 1943, a strike was called by local leaders of the Aluminum Workers of America at the Edgewater (N. J.) plant of the Aluminum Co. because of grievances arising from lay-offs. The strike was not sanctioned by the international president of the union.

After dismissal of the monopoly charges brought by the Government against the Aluminum Co. of America, the Department of Justice filed an appeal to the United States Supreme Court which was allowed in September 1942 and docketed for October 20. On November 23, the Clerk of the Supreme Court sent a letter to counsel for both sides stating that four justices had disqualified themselves from acting on the controversy and therefore the required quorum of six justices was not available. The Aluminum Co. immediately moved to dismiss the appeal. The Department of Justice asked the Court to deny the motion for dismissal, stating that "there is a possibility that, if the case is retained, legislation will be enacted empowering the Court to hear the appeal through those members of the Court qualified to participate."

On December 10, 1942, the New York State Court of Appeals upheld the Niagara Falls Power Co. and the Aluminum Co. of America against the State Waterpower and Control Commission in two decisions maintaining the status quo in regard to waterpower of the Niagara River.

During 1942 the Reynolds Metals Co., Federal Reserve Bank Building, Richmond, Va., completed an addition to its aluminum-reduction plant at Listerhill, Ala., bringing the annual capacity to 50,000 short tons, and this together with the 30,000-ton plant at Longview, Wash., brings the company total annual capacity to 80,000 tons. The year 1942 saw the completion of a sheet-rolling mill and rod mill at Listerhill, Ala., operated under the name of the Reynolds Alloys Co., and an extrusion plant at Louisville, Ky. At the instance of the Government, the sheet and rod facilities in Alabama are being increased in capacity by 12,000 tons, and negotiations have recently been concluded with the Defense Plant Corporation to further increase the company extrusion capacity.

The Olin Corporation (Western Cartridge Co.), East Alton, Ill., completed construction of its 20,000-ton aluminum-reduction plant

Digitized by Google

at Tacoma, Wash., during 1942 and began producing aluminum in September. Its subsidiary, Kalunite, Inc., constructed a 36,000-ton alumina plant at Salt Lake City, Utah, which will use alunite from Marysvale, Utah, as a raw material. The plant is expected to start operations before June 1, 1943. Both the alumina and aluminum plants were built with Defense Plant Corporation funds and are Government-owned.

Other companies that were enlarged or built new facilities in connection with the aluminum expansion program (chiefly with Defense Plant Corporation funds) were: Pennsylvania Salt Mfg. Co.—a 10,000-ton (annual) synthetic cryolite plant at Cornwells Heights, Pa.; Extruded Metals Defense Corporation—a 9,000-ton tubing and extrusion plant at Grand Rapids, Mich.; Bohn Aluminum & Brass Corporation—a 17,000-ton expansion to extrusion plant at Los Angeles, Calif.; Revere Copper & Brass Co.—extrusion plant at Baltimore, Md., and a 3,900-ton forging plant at Rome, N. Y.; Chevrolet Motor Division—a 59,040-ton forging plant at Saginaw, Mich., and a forged-cylinder-head plant at Anderson, Ind., with a capacity of 600,000 heads a year; Aluminum Forgings Co.—a 7,500-ton forging plant at Erie, Pa.; Chrysler Corporation—a 1,650-ton forging plant at Detroit, Mich.; Tube Turns, Inc.—a forged-cylinder-head plant with a 600,000-head annual capacity; Buick Motor Co., Flint, Mich., Wright Aeronautical Corporation, Lockland, Ohio, M. L. Oberdorfer Brass Co., Syracuse, N. Y., Servel, Inc., Evansville, Ind., Ford Motor Co., Detroit and Dearborn, Mich., National Bronze & Aluminum Foundry Co., Cleveland, Ohio, Dodge Motor Co., Chicago, Ill., Caterpillar Tractor Co., Peoria, Ill., and Nash-Kelvinator Corporation, Kenosha, Wis.—cast-cylinder-head foundries; and Great Lakes Carbon Corporation—a 90,000-ton calcined-petroleum-coke plant.

Secondary.—Recovery of secondary aluminum in 1942 totaled 198,492 short tons compared with 106,857 tons in 1941 and 80,362 tons in 1940. The 198,492 tons recovered from secondary sources included 14,104 tons of pure metal (98.5+ percent), 180,979 tons of aluminum alloys, 1,268 tons of aluminum in brass and bronze, 473 tons in zinc base alloys, and 1,668 tons of aluminum in chemical products (1,648 in aluminum chloride and 20 in sodium aluminate). Production in the form of secondary aluminum ingot totaled 144,694 tons (83,933 in 1941). The secondary aluminum recovered in 1942 required the consumption of 217,611 tons of aluminum scrap, 43,248 tons or 20 percent of which was old scrap (45,329 tons or 36 percent in 1941), and 174,363 tons or 80 percent new scrap (81,118, or 64 percent in 1941). Remelters, smelters, and refineries used 73 percent of this scrap; aluminum rolling mills, 26 percent; and foundries and other manufacturers, 1 percent. Additional information on secondary aluminum is given in the chapter on Secondary Metals—Nonferrous.

CONSUMPTION

Apparent domestic consumption of primary aluminum in 1942 increased 94 percent over 1941. Consumption of secondary aluminum increased at approximately the same rate.

Production, imports, exports, and apparent consumption of primary aluminum and production of secondary aluminum in the United States, 1938–42

Year	Primary aluminum					Secondary aluminum	
	Production		Imports (short tons)	Exports (short tons)	Apparent consumption [1] (short tons)	Short tons	Value [2]
	Short tons	Value					
1938	143,441	$56,659,000	[3] 8,870	6,309	89,523	38,800	$15,326,000
1939	163,545	64,600,000	9,290	36,632	167,646	53,947	21,309,065
1940	206,280	75,292,000	17,435	26,886	227,017	80,362	29,332,130
1941	309,067	100,395,000	13,358	7,405	302,788	106,857	34,707,153
1942	521,106	[4] 150,768,000	111,650	38,732	588,522	198,492	58,039,061

[1] Data not available on fluctuations in consumers' stocks. Withdrawals from producers' stocks totaled 31,443 short tons in 1939, and 30,188 in 1940; additions to producers' stocks totaled 56,479 tons in 1938, 12,232 in 1941, and 5,502 in 1942.
[2] Based upon average price of primary aluminum as reported to Bureau of Mines.
[3] Crude and semicrude, some of which may be secondary aluminum.
[4] Shipments.

Of the primary and secondary aluminum consumed in the form of fabricated products, about 60 percent went into airplane construction in airframes, landing gear, engines, propellers, and fittings. The greater part of the remainder was used in ship construction, tank engines, ordnance, and other military uses. Only a minimum of civilian needs, such as tools, some chemical equipment, and deoxidation in steel manufacture, were filled. Prewar uses of the metal, such as automobiles, trains, electrical conductors, furniture, household utensils, decorations, packaging, and bridge and building construction, have been virtually eliminated for the duration of the war.

Consumption of aluminum in 1943 will follow a pattern similar to that in 1942, but over-all consumption is expected to be nearly twice as large. Aircraft construction, which may reach 100,000 planes in 1943, will continue to demand the largest share of the available supply; Army, Navy, and Lend-Lease requirements will take most of the remainder; and indirect military and essential civilian consumption is expected to be allotted only about 8 percent of the total.

PRICES

Throughout 1942 the New York open-market base price of primary aluminum remained at 15 cents a pound for lots of 10,000 pounds or more, 99 percent plus pure ingot aluminum, delivered. Deductions allowed for transportation charges on orders of 500 pounds or more cannot exceed the lowest carload rate of rail freight. On December 5, 1942, the Aluminum Co. of America for the first time in recent years included pig aluminum in its price schedule. The price was set at 14 cents a pound for guaranteed 99 percent average minimum purity and is subject to the same transportation deductions as primary ingot.

Prices of fabricated and semifabricated products have been reduced substantially since the beginning of 1942. These reductions are attributed to mass production, manufacturing improvements, lowered operating costs, and continued research.

Price schedule No. 2, Aluminum Scrap and Secondary Ingot, was originally issued and effective March 24, 1941. During 1942 a total of 12 price actions was taken with respect to this schedule,

Digitized by Google

which was reissued effective February 17, 1942, embodying all previous amendments. Since that date, sales of idle inventories to Metals Reserve Co. at the order of the War Production Board have been exempt from the order; prices have been set on additional grades of scrap; all grades of obsolete scrap except pure cable have been reduced in price; payment for contaminated aluminum-containing

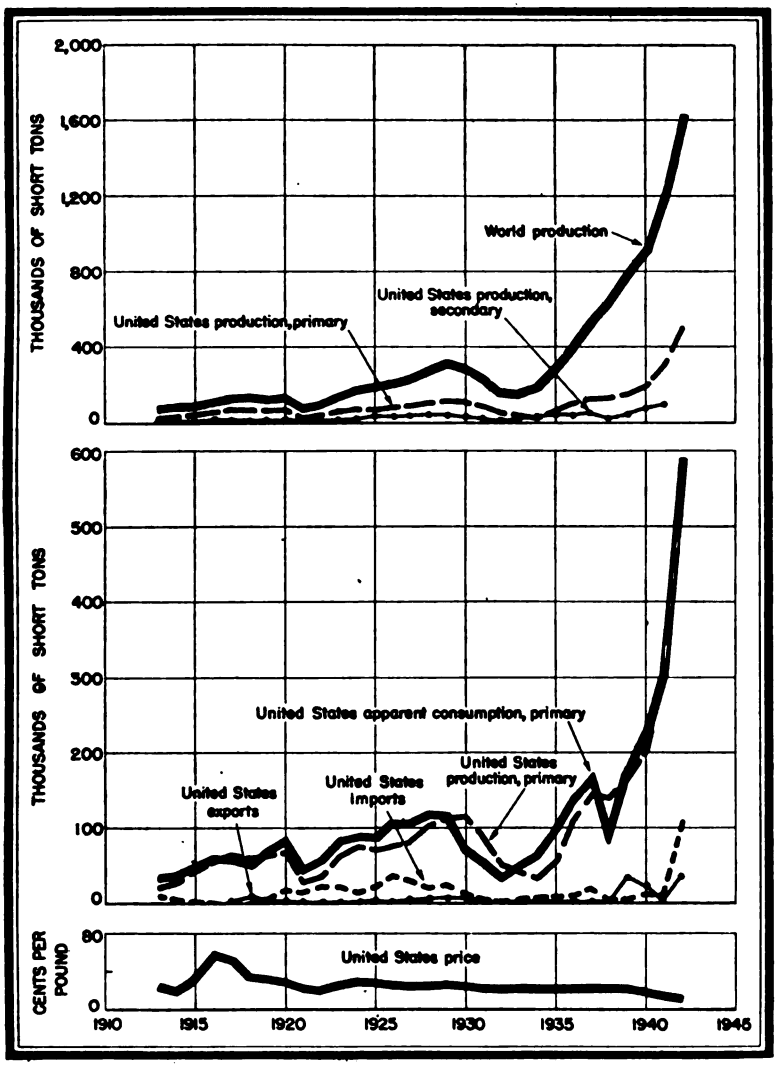

FIGURE 2.—Trends in production, imports and exports, apparent consumption, and average quoted prices of aluminum, 1913–42. Price is for No. 1 virgin 98–99 percent at New York through 1929, thereafter for 99-percent-plus virgin ingot, as reported by American Metal Market.

material has been limited to the actual metal contained; and a maximum price has been set for aluminum-bearing materials. On November 11, 1942, the Office of Price Administration announced that a premium of one-half cent a pound would be allowed in baled or packaged scrap sales to primary producers and 1 cent a pound for

Digitized by Google

briquetted scrap. On January 5, 1943, the Office of Price Administration announced the establishment of a maximum base price of 15 cents a pound for secondary ingot, and lower prices were set for low-grade alloys. The effect of this amendment was to rearrange and simplify the former classification of secondary ingot, and it had only a slight effect on prices.

FOREIGN TRADE

Imports and exports of crude and semicrude aluminum in 1942 were 736 and 419 percent more, respectively, than in 1941. The value of imports and exports of manufactured aluminum products increased 870 and 291 percent, respectively. Imports, exclusive of scrap, constituted 19 percent of the apparent consumption of primary aluminum in 1942. Of the imports of crude (105,795 short tons), less than 1 ton came from Curaçao and the remainder from Canada; of semicrude (5,855 tons), 5,799 tons came from Canada, 56 tons from Mexico, and less than 1 ton from other countries; and of scrap (487 tons), 464 tons came from Canada, 3 from Iceland, 2 from Panama, 8 from Canal Zone, 2 from Peru, 3 from New Zealand, 5 from Mexico, and less than 1 ton each from Curaçao, Cuba, Haiti, Venezuela, Chile, British East Africa, and the Bahamas.

Of the crude aluminum exported in 1942 (17,834 short tons), 439 tons went to Canada, 2 to Argentina, 1,704 to the United Kingdom, 4 to Australia, 111 to Brazil, 15,566 to U. S. S. R., 2 to India, 5 to China, 1 each to Chile and Surinam, and less than 1 ton to Canal Zone, Peru, and Egypt; of semicrude (20,898 tons), 3,715 tons went to the United Kingdom, 12,162 to U. S. S. R., and 5,021 to other countries; and of scrap (32 tons), all went to Canada.

Aluminum imported for consumption in the United States, 1940–42, by classes

Class	1940		1941		1942	
	Short tons	Value	Short tons	Value	Short tons	Value
Crude and semicrude:						
Metal and alloys, crude	17,435	$4,628,601	12,830	$3,333,642	105,795	$33,148,393

TECHNOLOGIC DEVELOPMENTS

One of the most important technologic advances of 1942 was the development of the lime-soda-sinter method for treating red mud tailings from the Bayer process. Lime-soda-sinter units are being constructed at the four Aluminum Co. of America alumina plants at Mobile, Ala., Baton Rouge, La., Hurricane Creek, Ark., and East St. Louis, Ill., and will operate in conjunction with the Bayer plants by a combination process developed in pilot-plant experimentation at East St. Louis. High-silica bauxite will be treated directly by the Bayer process, and the red mud tailings will be sintered with lime and soda ash in rotary kilns. The sintered material will be leached, and the sodium aluminate liquor thus obtained will be added to the Bayer liquors. No increase in alumina capacity is to be expected from this process; it is solely a means of extracting a larger percentage of alumina from high-silica bauxites than is possible by the Bayer method.

Much research was carried out in 1942 and early 1943 on the problem of obtaining alumina from clay and other materials. Kalunite, Inc., in its pilot plant at Salt Lake City has further developed and perfected its process for the production of alumina from Marysvale (Utah) alunite. By this process the alunite is crushed, roasted, and dissolved in sulfuric acid, after which the basic alum, formed by decomposition of crystallized potash alum, is sintered. The sintered product is leached, leaving the insoluble alumina behind.

Investigations and research on the extraction of alumina from clay, low-grade bauxite, and alunite, and on the beneficiation of aluminous ores are being carried out by the Bureau of Mines in its laboratories and pilot plants at Tuscaloosa, Ala.; Rolla, Mo.; Salt Lake City, Utah; Boulder City, Nev.; College Park, Md.; Norris, Tenn.; and Seattle, Wash.

Digitized by Google

The presence of minor alloying elements commonly found as impurities in aluminum was studied with respect to the allowable limits of impurities and their effect on the physical properties of aluminum casting alloys.[2] Continued expansion in capacity and number of sand casting foundries resulted in improved foundry techniques and greater output.[3] Advancement in plating on aluminum as the base material was marked in 1942,[4] and studies were made on the electrodeposition of aluminum on other metals.[5] The cleaning and finishing of aluminum used on warplanes received much attention.[6] Improved alloying technique and numerous patents for new alloys accompanied the expansion of fabricating facilities.[7] The Aircraft Parts Division of the Reynolds Metals Co. is producing finished aircraft parts at its Louisville, Ky., plant and shipping them direct to aircraft manufacturers, thereby greatly reducing the usual 3- to 6-month delay in scrap return when sheet instead of finished parts is shipped.[8]

Anhydrous aluminum sulfate can be produced from commercial aluminum sulfate by a process that avoids the mechanical difficulties caused by transformation of the salt through a fluid, sticky stage previously considered unavoidable (U. S. Patent 2,304,519). A new process has been developed for the production of an aluminum chloride catalyst by soaking pieces of a suitable carrier material in a bath of molten anhydrous aluminum chloride (U. S. Patent 2,295,977).

WAR MEASURES

Mandatory priorities restricting delivery, processing, use, and inventories, which had been placed on aluminum by the Office of Production Management on March 22, 1941, were kept in force throughout 1941 and 1942. The original order, M–1, was changed and revised by the War Production Board. The order in force on April 1, 1943, was M–1–i, effective August 18, 1942, and last amended November 20, 1942; it provides for complete allocation control of virgin and secondary metal.

Order M–1–d, covering aluminum scrap containing more than 15 percent aluminum, became effective January 7, 1942, and prohibits the use of scrap, except home scrap, without the authority of the Director of Industry Operations. The order does not apply to virgin-aluminum producers or approved smelters. Each plant generating 1,000 pounds or more of scrap must segregate scrap at the machine and all 17S, 24S, and 52S alloy scrap in solid form must be sold to Aluminum Co. of America or Reynolds Metals Co. Other segregated scrap must be sold to these companies or approved dealers and smelters and the identity of segregated scrap must be certified to by the seller.

Manufacture and sale of aluminum pigments and paints was prohibited by order M–1–g effective March 10, 1942.

On August 1, 1942, order M–1–h, fully allocating bauxite and alumina, became effective. For the purpose of this order bauxite was defined as "restricted" and "nonrestricted." Restricted bauxite (containing less than 15 percent silica) was further subdivided into high-silica restricted (8 to 15 percent silica) and low-silica restricted (less than 8 percent silica). The purpose of the order is to make certain that the higher grades of ore are allocated to the most essential needs and that no user who can use nonrestricted ore receives any of the high-grade material. Alumina and primary alumina products are stringently controlled by the order in an effort to divert all possible calcined alumina to the aluminum industry and essential abrasive uses, and small quantities of primary alumina products are manufactured and allocated to essential uses, largely refractories, catalysts, and the production of certain chemical products.

On November 2, 1942, the War Production Board announced a new long-range plan for controlling the flow of critical materials into war uses—the widely heralded Controlled Materials Plan. Under it, requirements for critical materials will be adjusted to the available supply, and the quantity and type of materials required will be available at the time and place necessary to meet approved programs. The plan, in effect a vertical allotment system, was applied to the three most basic and critical materials—aluminum, copper, and steel—and became effective in its transitory stages in the second quarter of 1943. The former horizontal allotment system—the Production Requirements Plan—will be completely replaced by the Controlled Materials Plan by July 1, 1943, for the above-mentioned critical materials.

WORLD BAUXITE AND ALUMINUM INDUSTRIES

Production and consumption of aluminum reached an unprecedented record in 1942, and this high mark will be considerably exceeded in 1943; most of the increase will be from expanded facilities in North America.

[1] Estimated production. Estimates for 1939, 1940, 1941, and 1942 by the authors.

World production of bauxite is estimated to have reached approximately 8,276,000 metric tons in 1942, 24 percent more than in 1941 and 114 percent more than in the pre-war year 1938. Of the world output in 1942, it is thought that the production in Axis dominated or controlled territories was 2,876,000 tons or 35 percent and that 5,400,000 tons or 65 percent was under United Nations control.

The aluminum produced in 1942 is estimated to have totaled 1,491,000 metric tons, 35 percent more than in 1941 and 158 percent more than in 1938. Of the world output in 1942, it is thought that production under the control or domination of the Axis in Europe and the Far East was 612,800 tons, or 41 percent, and under total United Nations control 878,200 tons, or 59 percent.

REVIEW BY COUNTRIES

Australia.—Bauxite is mined at Bundanoon, New South Wales, for use as a flux in steel manufacturing by Broken Hills Proprietary, Ltd., and at Nahoo and Boolara, Victoria, for chemical purposes and alumina production by Sulphates, Ltd., at Melbourne. According to present plans the production of bauxite will not exceed 5,000 tons in 1943. Sulphates, Ltd., the only producer of alumina in the Commonwealth, has a plant of 1,000 tons annual capacity and successfully uses a sodium bisulfate process developed by Michael Martin as an improvement on the Penniakoff process. It is reported that an acid process using ammonium sulfate is under consideration in plans for a possible expansion of alumina capacity. Proposals to erect a reduction plant at Sydney apparently have not yet materialized and may have to wait until after the war. Fabricating facilities have been greatly expanded, and it is reported that consumption of ingot has nearly doubled.

Brazil.—Construction has been nearly completed on the 10,000-ton alumina plant and 2,000-ton reduction plant of the Companhia Electro-Chimica Brasileira at Saramenha, near Ouro Preto, Minas Gerais. These plants will be able to fill present Brazilian domestic needs for alumina and aluminum. The Gambe deposit near Ouro Preto with a 2,000,000-metric ton reserve will supply the alumina

Digitized by Google

plant with ample high-grade material. Negotiations have been continuing between Brazil and the United States to obtain equipment for mining the Pocos de Caldas deposits and for the construction of a 40,000-ton alumina plant and a 20,000-ton reduction plant near São Paulo. The bauxite deposits on the Pocos de Caldas Plateau are said to contain 7,000,000 tons of proved reserves. Estimates by the Brazilian Government indicate 120,000,000 tons of possible ore. Analyses of the bauxite range from 57 to 61 percent Al_2O_3, according to a reliable source. Power for the reduction plant would be obtained from standby power from the São Paulo Tramway Light & Power Co. at Serra Cubatao and from two additional units to be constructed. Exports of bauxite from Brazil in 1942 totaled 12,397 metric tons compared with 14,365 tons in 1941.

British Guiana.—Exports of bauxite by the Demerara Bauxite Co., Ltd., and the Berbice Co., Ltd., totaled 1,116,463 long tons in 1942, of which 872,138 tons went to Canada, 204,750 to the United States, 39,574 to the United Kingdom, and 1 to Trinidad. The Berbice Co., Ltd., began sending dried bauxite by barge from its property 130 miles up the Berbice River to the loading point of Everton in the early spring of 1942 for shipment to Canada. This company has been shipping bauxite solely to Canada. The Demerara Bauxite Co., Ltd., is reported to have opened up a new deposit of bauxite 40 miles up river from the port of MacKenzie. The Demerara River was being dredged in late 1942 to facilitate transport of ore by allowing deeper draught vessels to load farther upstream.

Canada.—Compared with 1942, Canadian aluminum production is expected to increase more than 50 percent in 1943. The estimated rate of production to be attained in 1943 is 508,000 tons. The gigantic facilities of the Aluminum Co. of Canada for alumina and aluminum at Arvida, Quebec (1,050,000-ton alumina plant and 360,000-ton reduction plant) are by far the largest in the world and at capacity will supply nearly one-fourth of the metal to be produced annually in the Western Hemisphere. Other Canadian reduction plants, all owned by the Aluminum Co. of Canada, are at Shawinigan Falls (75,000 tons capacity), Beauharnois (25,000 tons capacity), Le Touque (25,000 tons capacity), and Isle Maligne (15,000 tons capacity). With the exception of one potline at Isle Maligne all the above plants were in full operation on May 1, 1943. A lime-soda-sinter plant will be completed in the third quarter of 1943 at Arvida for use in conjunction with the present Bayer facilities if the shipping situation should deteriorate further and necessitate the importation of relatively high-silica Arkansas bauxite from the United States. Since 1939 aluminum-fabricating facilities have been greatly expanded, principally at Kingston, Ontario, where strong-alloy sheet, extrusions, and forgings are made, partly for United States consumption. Rolled screw machine and rivet stock is produced at Shawinigan Falls, Quebec, and sheet and castings at Toronto, Ontario. At Toronto a new sand-casting foundry is producing 200,000 pounds of castings a month. The Kingston forging plant is turning out 10,000 propeller blades a month, most of which are for the United States.

To save shipping space bauxite cargoes from British Guiana and Surinam were unloaded largely at eastern United States ports, principally New York, and then shipped by rail or rail and barge to the alumina plant at Arvida.

Central America.—Bauxite deposits have been reported from Nicaragua, Honduras, and El Salvador. No definite information is available on grade or reserves, but exploration is being pressed.

China.—Large deposits of aluminous material have been discovered in western China in the Provinces of Yunnan and Szechwan. It is reported that exploitation will be undertaken by the Chinese Economic Ministry.

Colombia.—A deposit of bauxite has been reported in the region of San Martin, Intendencia del Meta.

France.—French aluminum production in 1941 was only 62,200 tons, falling short of its objective of 70,000 tons by about 10 percent. Fuel, power, and rail shortages probably were the primary causes, aided by labor shortages and labor troubles. Production in the first quarter of 1942 is reported to have been at a rate slightly exceeding 70,000 tons. The well-known French firm of Alais, Froges & Camargue (Pechiney) is understood to have expanded its capacity by constructing two new plants at the suggestion of the Germans. The company capital was doubled to more than 800,000,000 French francs to make the expansion possible. During 1942 alumina was exported to Germany, and there is reason to believe that a substantial share of this was reshipped to Norway. According to Vichy several hundred French prisoners of war were sent back from Germany to work in the bauxite mines in the Brignoles area.
